What is μe Conversion?

$$R_{\mu e} \equiv \frac{\Gamma(\mu^- + (A, Z) \rightarrow e^- + (A, Z))}{\Gamma(\mu^- + (A, Z) \rightarrow \nu_\mu + (A, Z - 1))}$$

- μ changes into e in the field of a nucleus without ν emission
- Charged Lepton Flavor Violation (CLFV)
- Related Processes: $\mu \rightarrow e\gamma$, $\mu \rightarrow e^+e^-e$, $K_L \rightarrow \mu e$

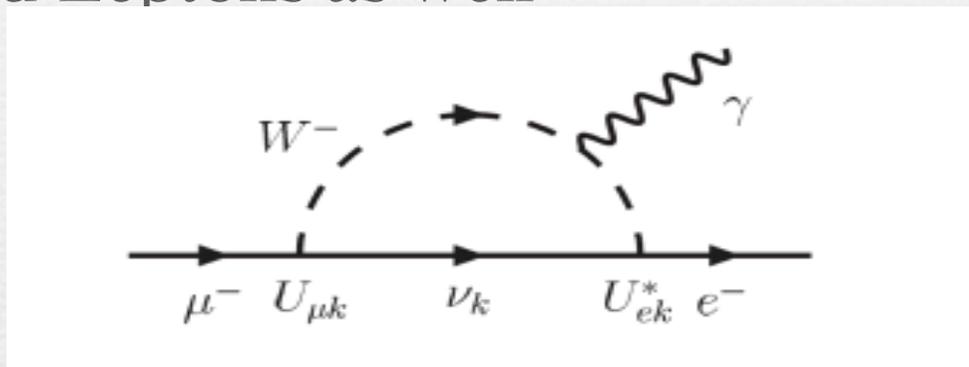

Motivation

- ν 's have mass! Therefore individual lepton numbers are not good quantum numbers
- Therefore Lepton Flavor Violation occurs in Charged Leptons as well

- Except neutrinos have to change flavor in loop...

$$\text{BR}(\mu \rightarrow e\gamma) = \frac{3\alpha}{32\pi} \left| \sum_{i=2,3} U_{\mu i}^* U_{ei} \frac{\Delta m_{1i}^2}{M_W^2} \right|^2 < 10^{-54} \text{ ☹️}$$

- But this is good! New physics not hidden by boring old neutrino oscillations (yesterday's signal is today's calibration is tomorrow's background)

Contributions to μe Conversion

Neutrino Mass

SuperSymmetry

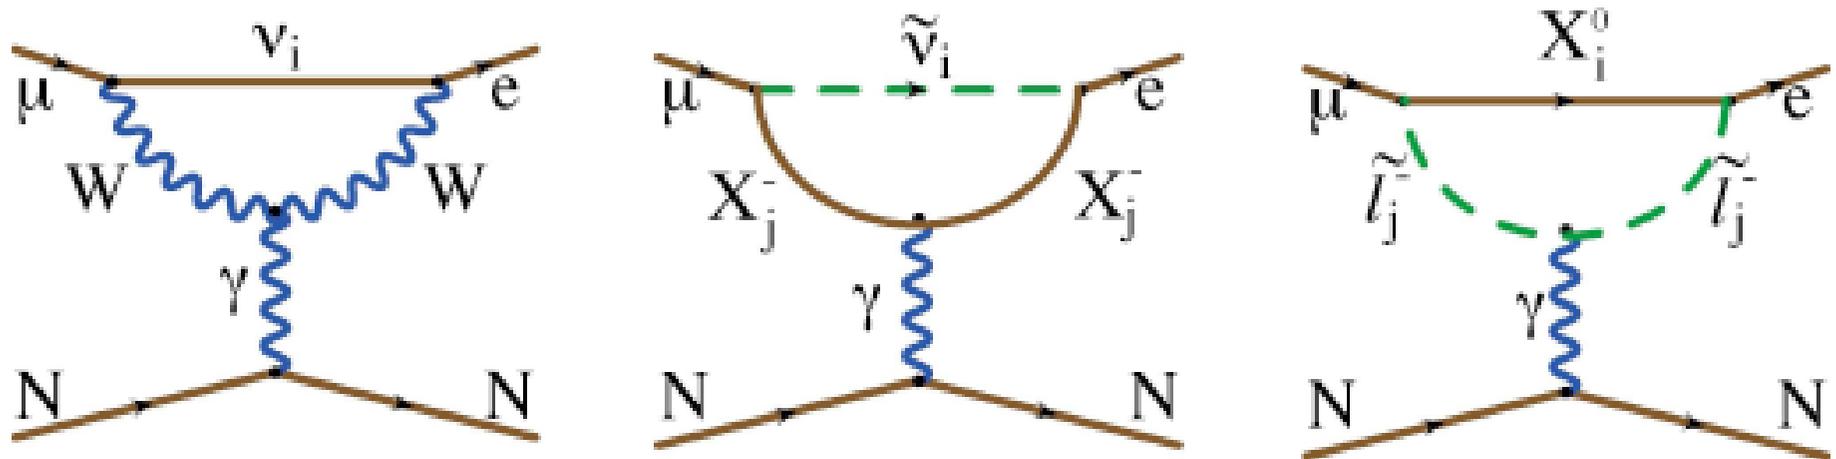

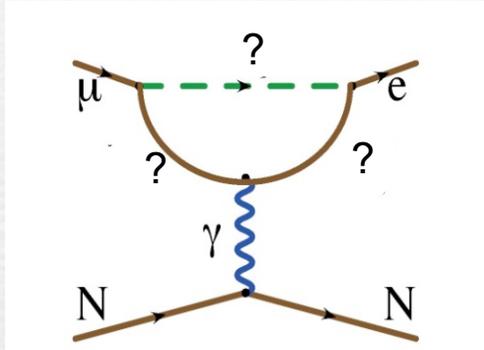

Figure 1.1: The leading Standard Model diagram for $\mu+N \rightarrow e+N$ is shown on the left. The center and right figures are the dominant SUSY diagrams.

- Probe of Supersymmetry; complementary to LHC and pushes beyond LHC sensitivity
- Observation of neutrino mass, interpreted in SeeSaw, points to observable CLFV in many models [Blanke et al., hep-ph/0702136](https://arxiv.org/abs/hep-ph/0702136)

μe Conversion and $\mu \rightarrow e \gamma$

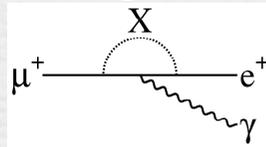

μ Dipole/Penguin

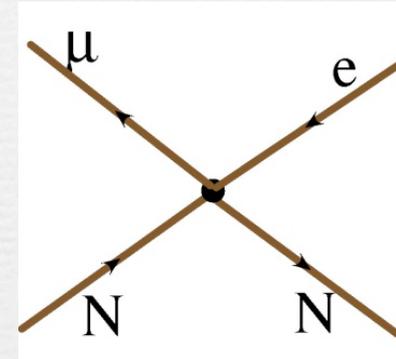

κ

This type of diagram gives rise to small CLFV through virtual neutrino mixing

Also contributes to $\mu \rightarrow e \gamma$ if photon real

μ Fermi Interaction

Λ

Corresponds to exchange of a new, massive flavor-changing neutral current particle

$$\frac{1}{\Lambda^2} = \frac{f^2}{16\pi^2} \frac{1}{M_{\text{new}}^2}$$

Does not produce $\mu \rightarrow e \gamma$

$$\mathcal{L}_{\text{CLFV}} = \frac{m_\mu}{(\kappa + 1)\Lambda^2} \bar{\mu}_R \sigma_{\mu\nu} e_L F^{\mu\nu} + \frac{\kappa}{(1 + \kappa)\Lambda^2} \bar{\mu}_L \gamma_\mu e_L (\bar{u}_L \gamma^\mu u_L + \bar{d}_L \gamma^\mu d_L)$$

$\mu \rightarrow e\gamma$ and μe Conversion

Experimental Differences

$\mu \rightarrow e\gamma$

- time coincidence of back-to-back monoenergetic particles
- limited by accidental coincidences: $\mu \rightarrow e\nu\nu$ and occasional coincidence with photon leads to limit of $10^{-(13-14)}$ (for acceptable rate/running time)
- signal e, γ in same energy region as backgrounds**

$\mu \rightarrow e$ conversion

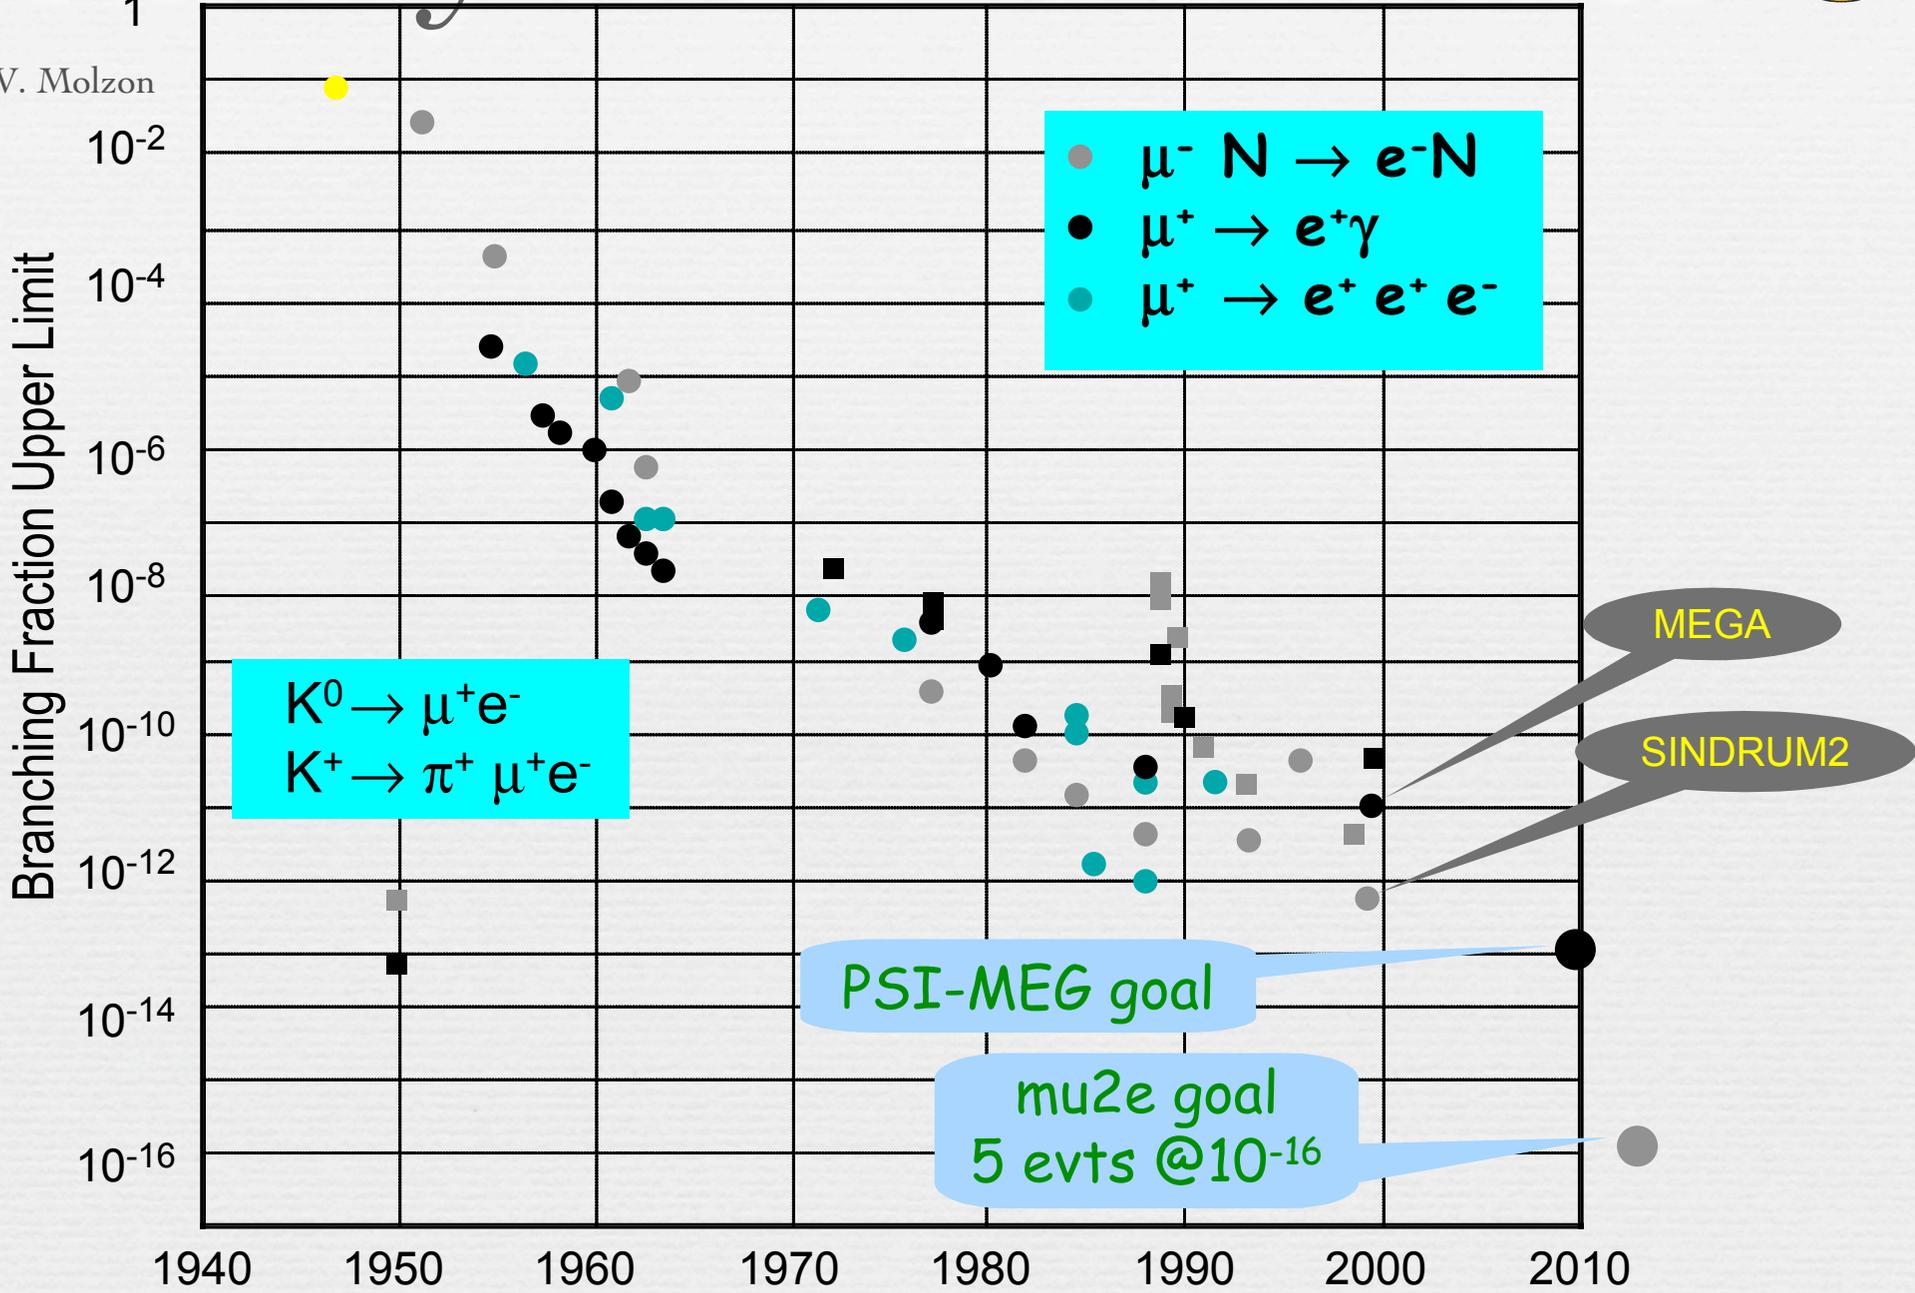

- single, nearly monoenergetic particle
- single particle signal is a disadvantage, but:
- signal electron at much higher energy region than almost all background**

Quick Tour of Expt

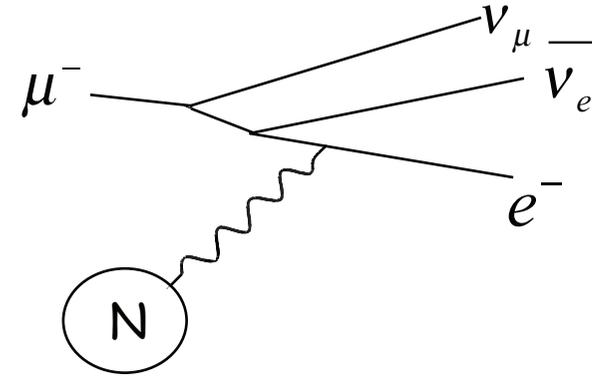

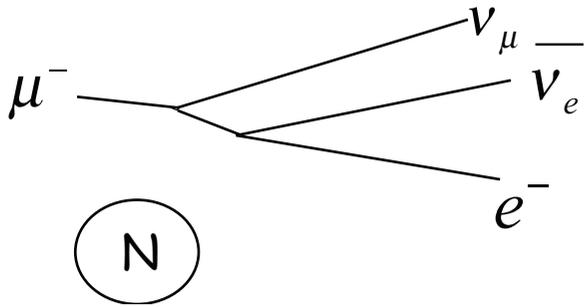

Major Background Types

- Decay In Orbit:
 - Muon Captured in Stopping Target: muon decays into electron, electron energy near signal
 - Radiative μ Capture: $\mu \text{ Al} \rightarrow \gamma \nu_{\mu} \text{ Mg}$
- Prompt:
 - Protons Hit Production Target, produce π 's neutrons, and antiprotons which produce $\gamma \rightarrow e^+ e^-$, sometimes with energy near $\mu \rightarrow e$ signal

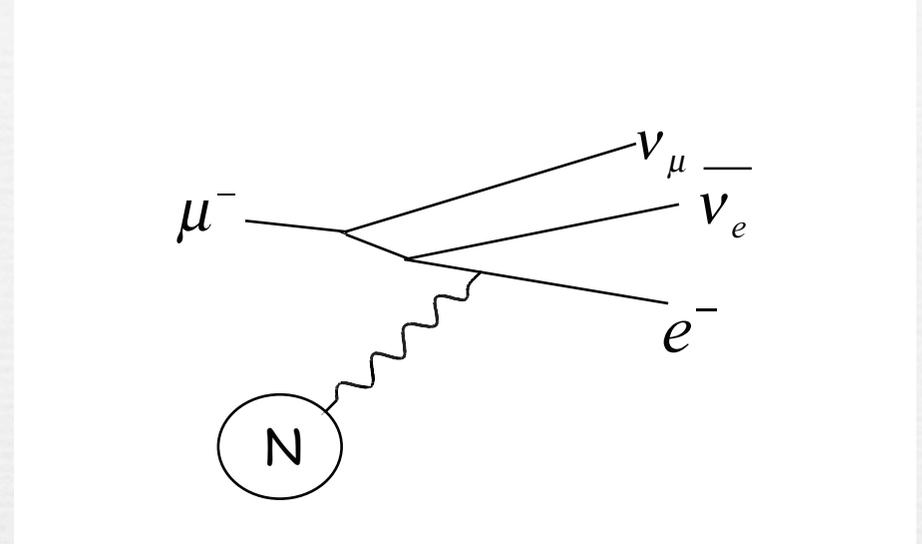

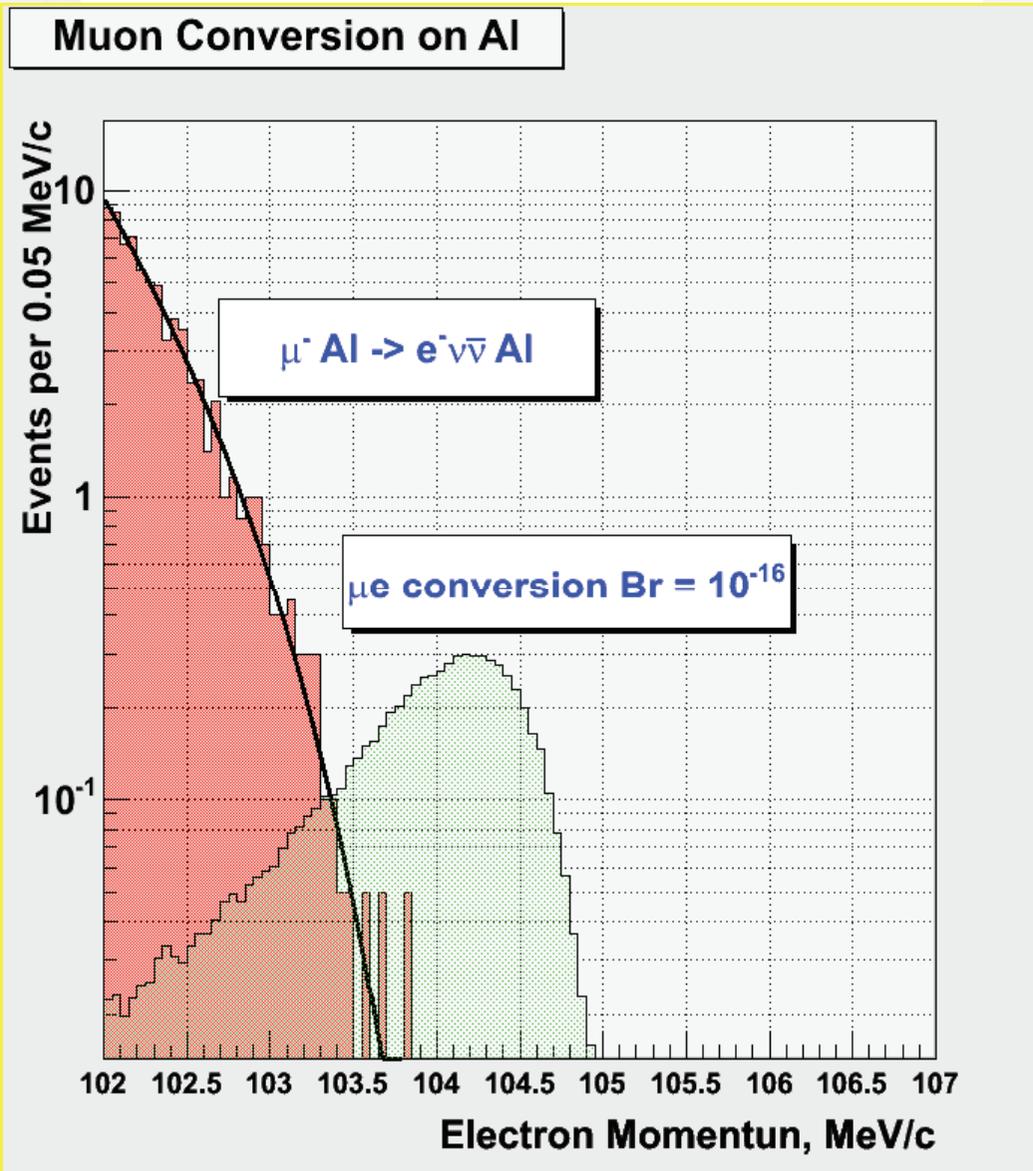

Decay-in-Orbit Background

- High Rate
- Peak 52.8 MeV
- Detector *insensitive* to these

- Fraction within 3 MeV of signal is 5×10^{-15}
- Rate falls as $(E_{\max} - E)^5$
- Drives Resolution Requirement

Decay-in-Orbit Background

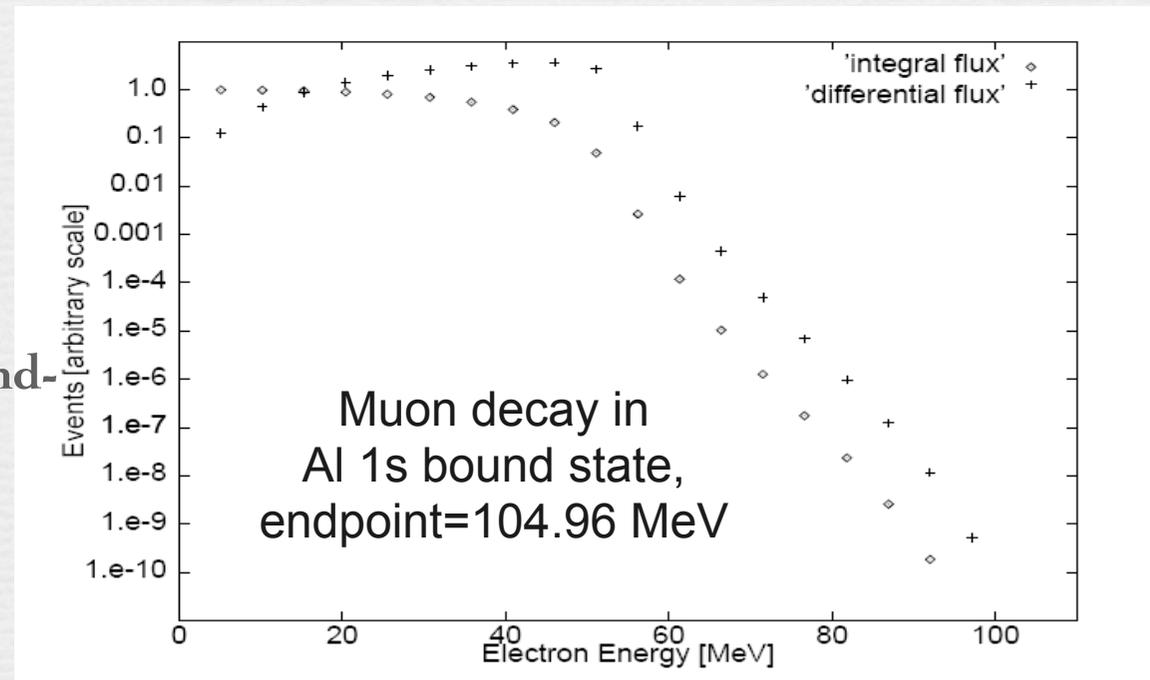

- Fraction within 3 MeV of signal is 5×10^{-15}
- Rate falls as $(E_{\text{max}} - E)^5$
- Drives Resolution Requirement

Decay-In-Orbit Details

- $E_e(\text{max}) = (m_\mu c^2 - \text{Nuclear Recoil Energy} - \text{Atomic Binding Energy})$
- For $Z=13$ (Al), Atomic BE=0.529 MeV, Recoil energy=0.208 MeV $\rightarrow E_e(\text{max}) = 104.96$ MeV
- Rate near the maximum energy falls very rapidly. Near endpoint: proportional to $(E_e(\text{max}) - E)^5$
- Major potential source of background - Discriminate against it with good electron energy resolution, ~ 1 MeV FWHM for $\mu 2e$

looks exactly like signal except for electron energy

Prompt Backgrounds

- Prompt: particles produced by proton pulse which interact almost immediately when they enter the detector region: π , neutrons, pbars

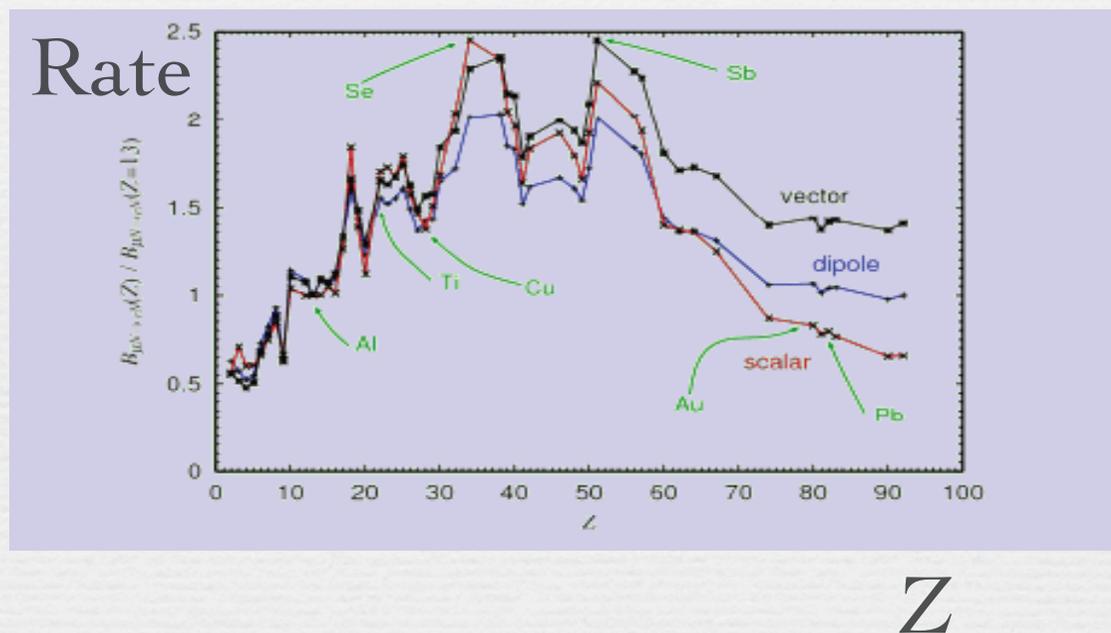

- Radiative pion capture, $\pi^- + A(N, Z) \rightarrow \gamma + X$.
 - γ up to m_π ; $\gamma \rightarrow e^+e^-$; if one electron ~ 100 MeV in the target, looks like signal. Major limitation in best existing experiment, SINDRUM II.
- Beam electrons: incident on the stopping target and scatter into the detector region. Need to suppress e^- with $E > 100$ MeV near signal
- In-flight muon decays yielding electrons: since not stopped, can have enough momentum to fake signal (> 76 MeV/c)

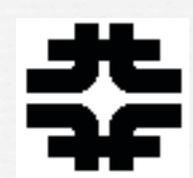

Choice of Stopping Material

- Stop muons in target (Z,A)
- Physics sensitive to Z: with signal, can switch target to probe source of new physics
- Why start with Al?

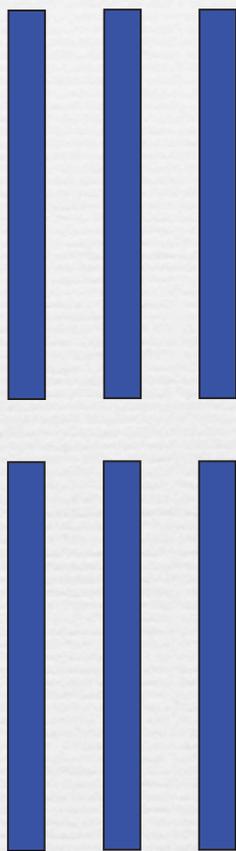

rate normalized to Al

Signal in Stopping Target

target foils

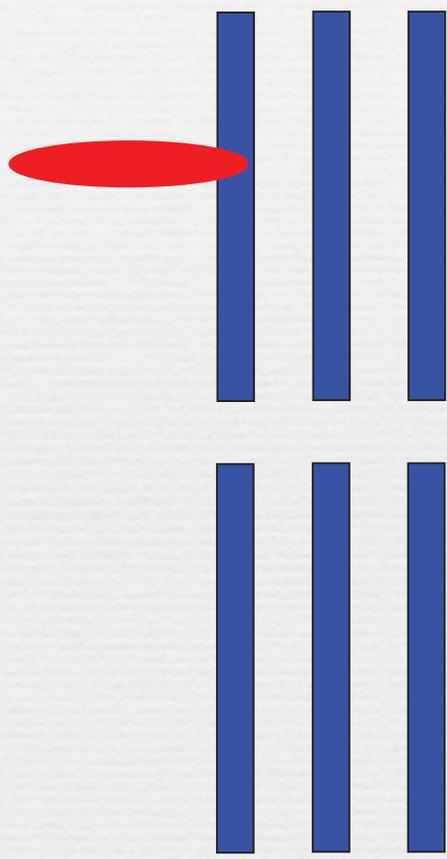

Signal in Stopping Target

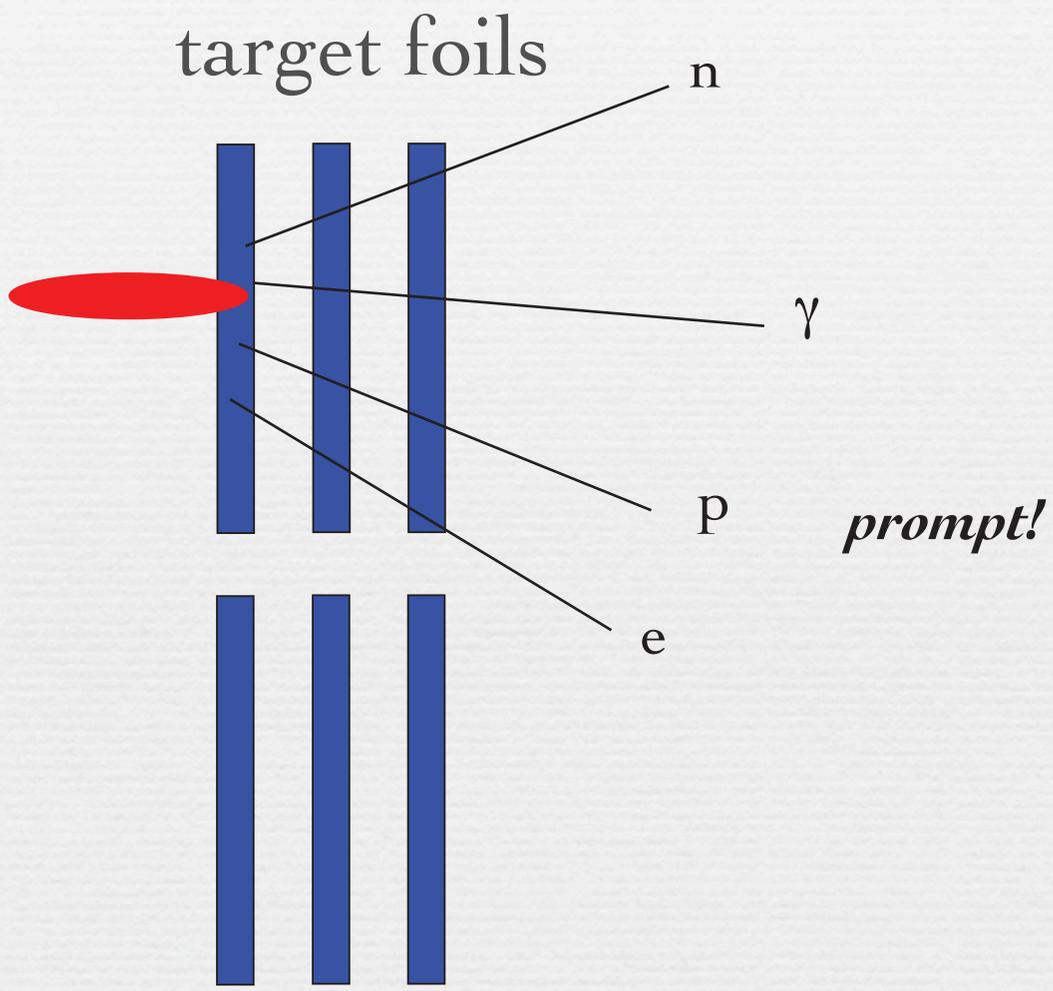

target foils

prompt!

delayed 105 MeV electron

Signal is single, monoenergetic electron occurring after bunch passes: want this delay to be long to reduce prompt

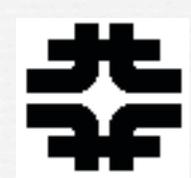

Signal in Stopping Target

- need good momentum resolution
- need particle ID (calorimeter)
- need a bunched beam!

prompt!

Signal is single, monoenergetic electron occurring after bunch passes: want this delay to be long to reduce prompt

Prompt Bkg and Choice of Z

- choose Z based on tradeoff between rate and lifetime: longer lived reduces prompt backgrounds

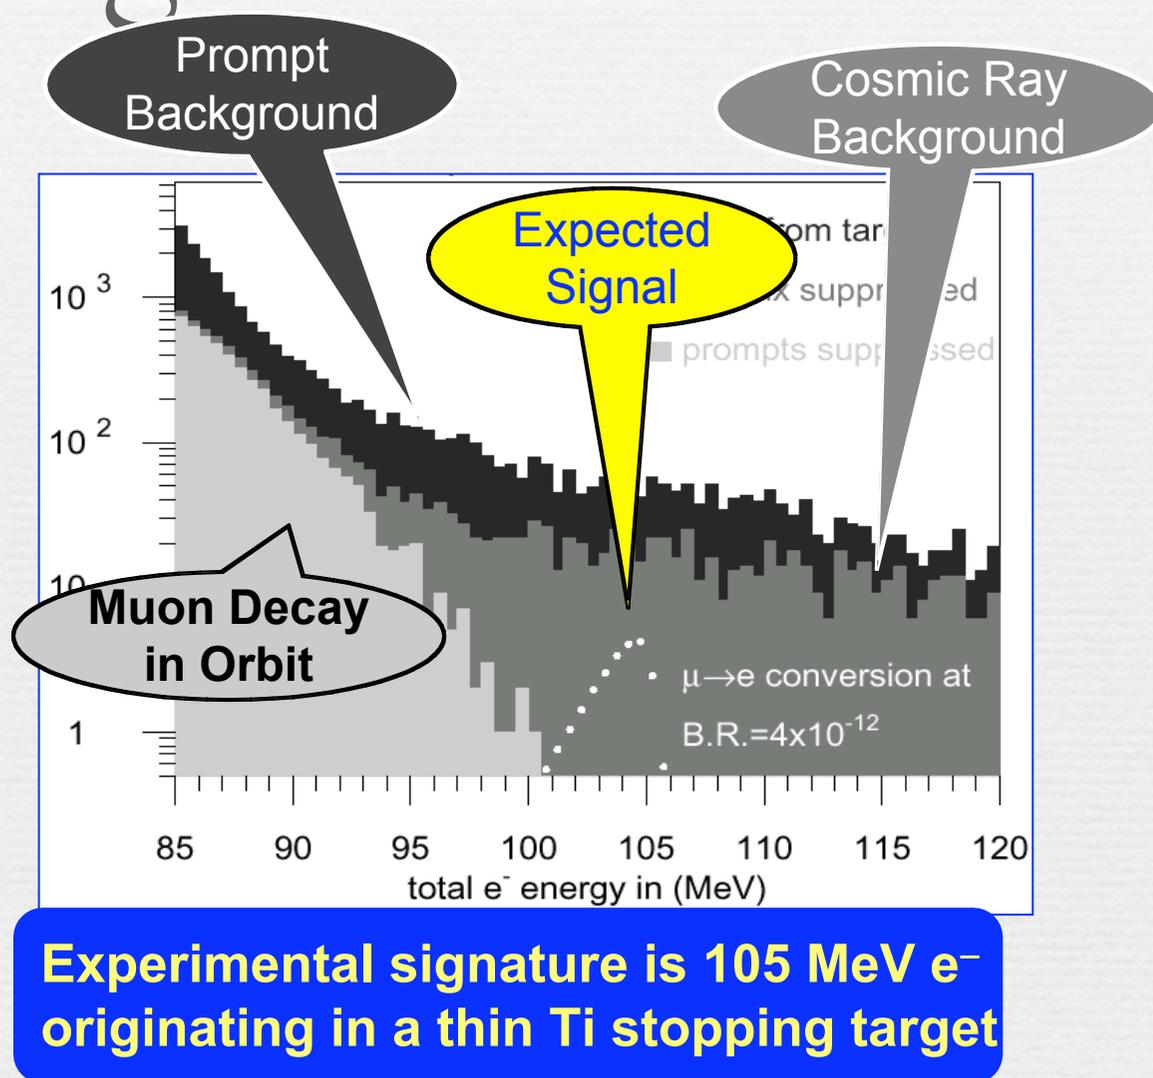

Nucleus	$R_{\mu e}(Z) / R_{\mu e}(Al)$	Stop-to-Capture Time	Atomic Bind. Energy (1s)	Conversion Energy	Prob decay >700 ns
Al(13,27)	1.0	880 nsec	0.47 MeV	104.96 MeV	0.45
Ti(22,~48)	1.7	328 nsec	1.36 MeV	104.18 MeV	0.16
Au(79,~197)	~0.8-1.5	72.6 nsec	10.08 MeV	95.56 MeV	negligible

too short for FNAL beam pulse; need short pulse to eliminate prompt backgrounds

Existing Limits

- $R_{\mu e} < 6.1 \times 10^{-13}$
in Au
(SINDRUM-II)
- Want to probe to 10^{-16} or better
- Factor of $\approx 10^4$
improvement
non-trivial

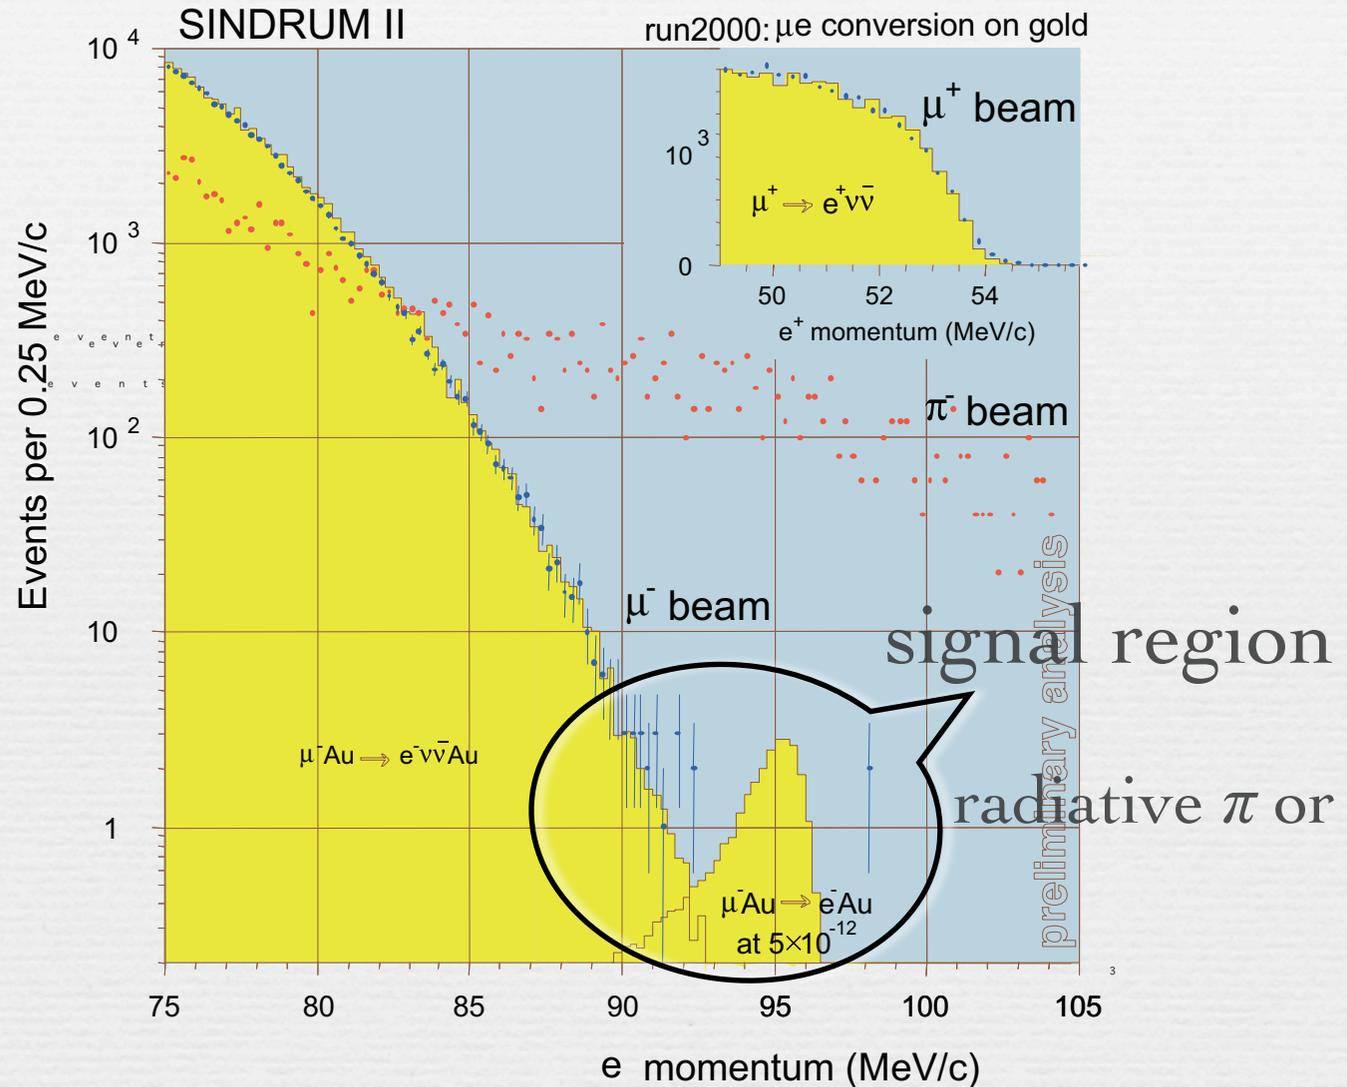

SINDRUM II Results

Final SINDRUM-II on Au

Note Two Background Events past Signal Region

Multiply Problems by 10⁴ ?

July 14, 2001

HEP 2001 (W.Berti - SINDRUM II collaboration)

Key Improvement of Both COMET and $\mu 2e$

PSI PAUL SCHERRER INSTITUT

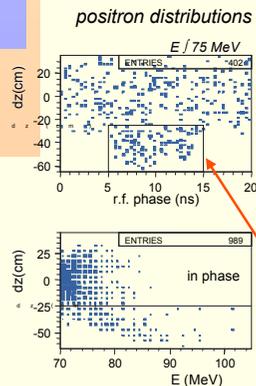

Background : b) pion induced

Radiative Pion Capture (RPC) : $\pi^- Au \rightarrow \gamma + Pt^*$ followed by $\gamma \rightarrow e^+ e^-$

Kinematic endpoint of photon spectrum around 130 MeV! Branching ratio of order 2%.

No way to distinguish an asymmetric $e^+ e^-$ -pair (with little e^+ energy and e^- energy at 95 MeV) from μe !

\Rightarrow Needs strong pion suppression : only ~ 1 pion every 5 minutes is allowed to reach gold target!

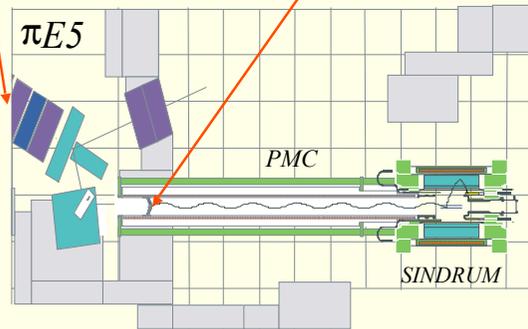

July 14, 2001

BUT: Degraded pion stop target $\rightarrow e^+ e^-$ pairs from RPC are collected by B_{PMC} and transported towards the gold target where they may scatter into spectrometer acceptance (typ. forward scattering)

\Rightarrow use solid angle and cyclotron phase correlation to cut.

\Rightarrow tune beamline to suppress high momentum tail

\Rightarrow use **degrader** 8m in front of gold target to separate μ 's and π 's by their different stopping power. Penetrating slow pions decay in PMC.

HEP 2001 (W.Bertl - SINDRUM II collaboration)

SINDRUM:
 a) straight line from target to detector
 b) continuous beam

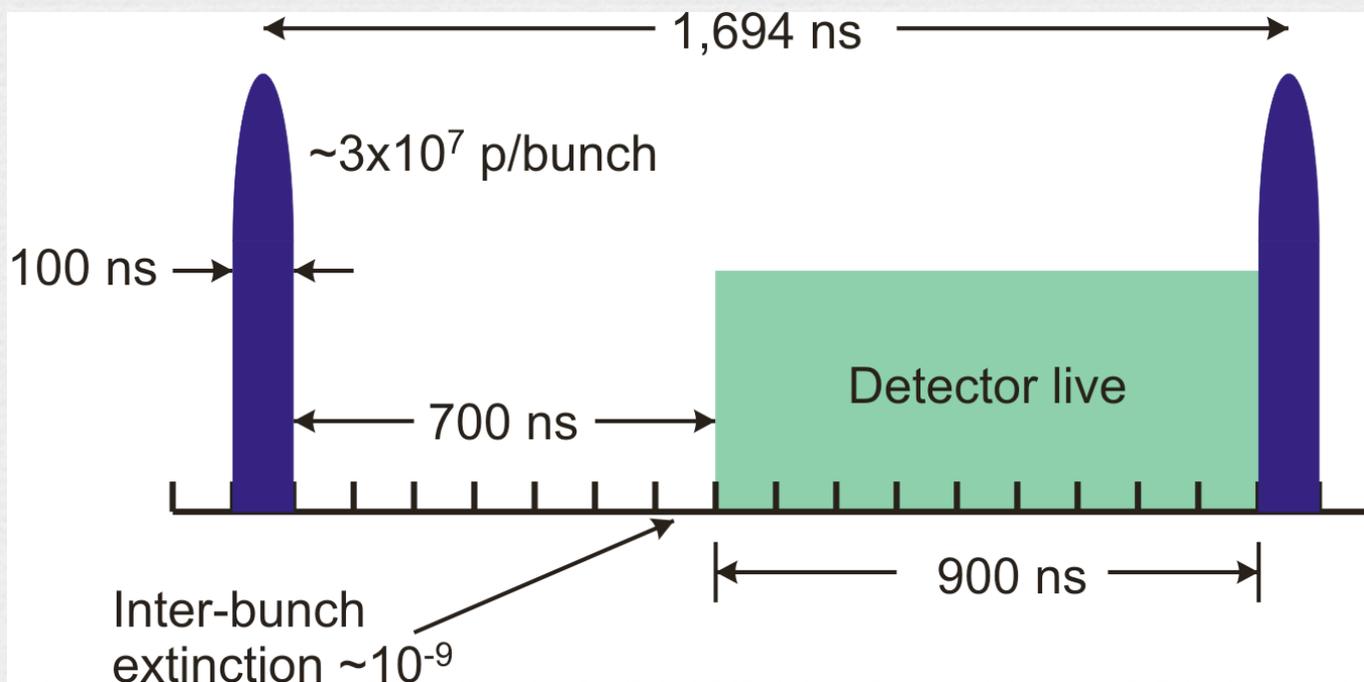

$\mu 2e$ at FNAL

- Improvements:
 - $>10^3$ increase in muon intensity from SINDRUM
 - Curved Transport Solenoid and Pulsed Beam to Eliminate prompt backgrounds (Radiative π)
 - SINDRUM was continuous beam
 - in $\mu 2e$, pulsed beam! but must achieve required 10^{-9} extinction *and measure it*
 - Tracker Resolution Critical for Decay-In-Orbit Rejection

Pulsed Beam

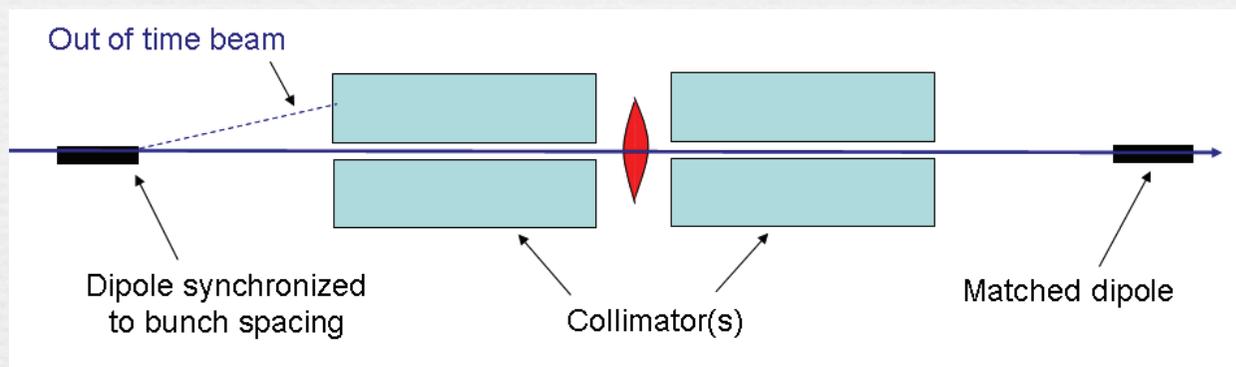

- Beam pulse duration $\ll \tau_\mu$, Pulse separation $\approx \tau_\mu$
- Large duty cycle 75-90% depending on scheme
- Extinction between pulses $< 10^{-9}$ needed
 - # protons out of pulse/# protons in pulse

Measuring Extinction Rate

- Protons in beam between pulses:

- “Switch” dipole timing to eliminate bunches, accept out-of-time protons for direct measurement
- Other schemes under investigation
 - Measurement: off-angle collimators and telescope?

Outline of Remainder

- Beam pre- and post-Project X:
 - how do we get muons to target? how many? time structure?
- Detector:
 - How Do We Achieve Required Rejection and Resolution?
- Before we get into details on rates, how does this compare to MECO?

Quick Fermilab

Glossary

Booster:

- The Booster accelerates protons from the 400 MeV Linac to 8 GeV

Accumulator:

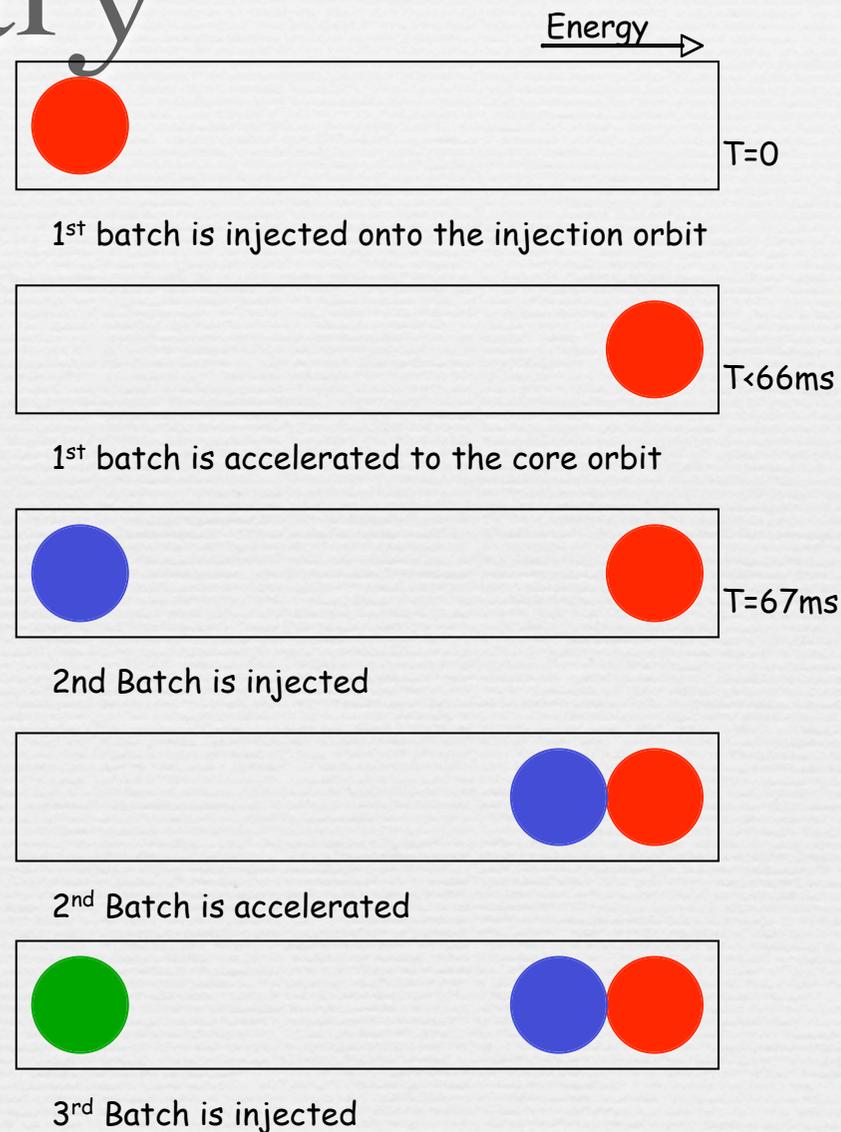

- momentum stacking successive pulses of antiprotons now, 8 GeV protons later

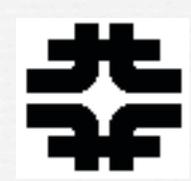

Debuncher:

- smooths out bunch structure to stack more \bar{p} now; rebunch for mu2e

Recycler:

- holds more p than Accumulator can manage, "store" here

NovA Era and $\mu 2e$

- Load from Booster to Recycler; Booster 'ticks' at $4E12, 15$ Hz

booster batches

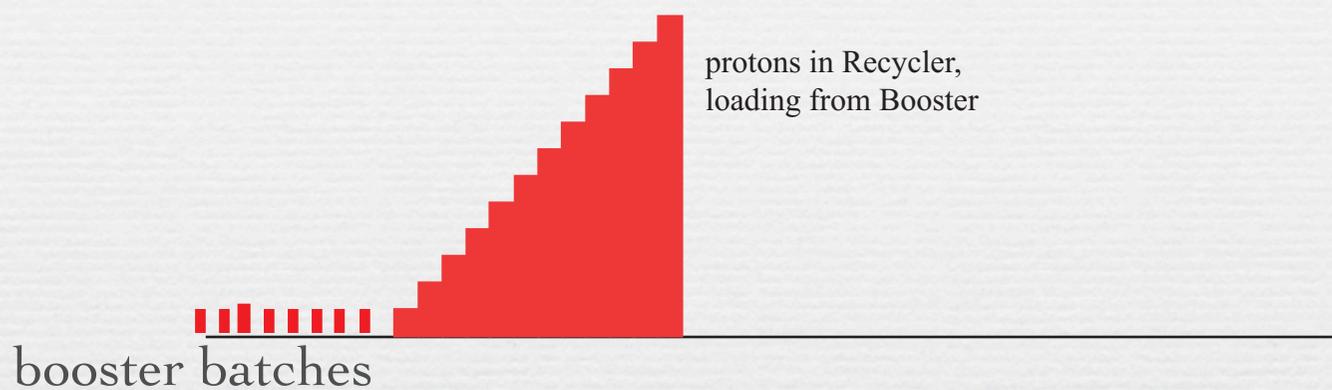

- Single-Turn Transfer to MI

NovA Era and $\mu 2e$

- Load from Booster to Recycler; Booster 'ticks' at $4E12, 15 \text{ Hz}$

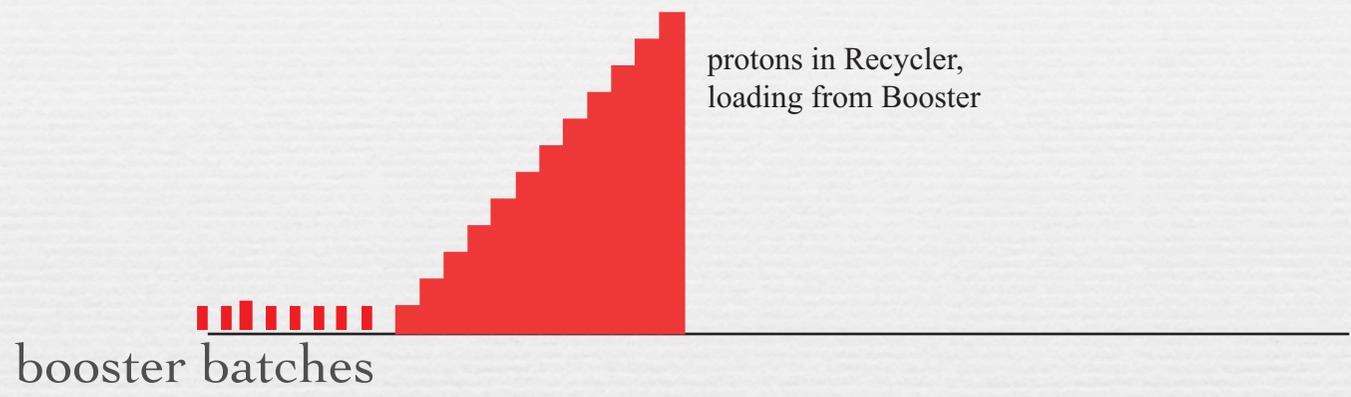

- Single-Turn Transfer to MI

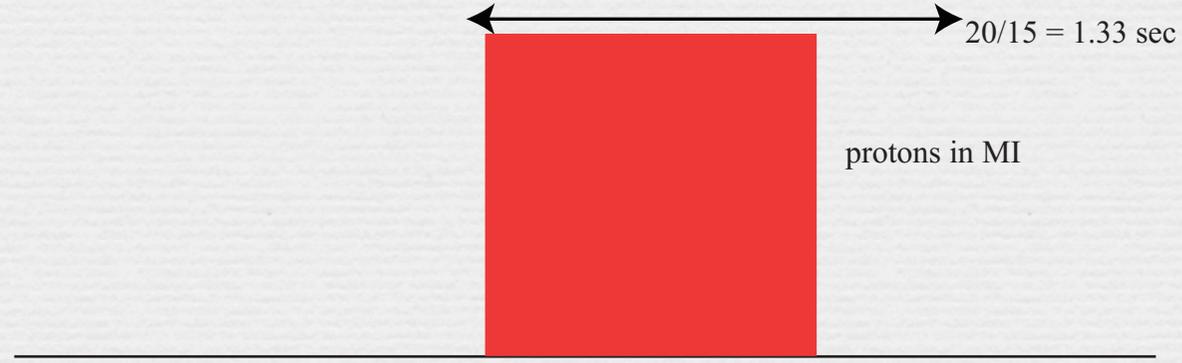

NovA Era and $\mu 2e$

- Single-Turn Transfer to MI

All Together...

All Together...

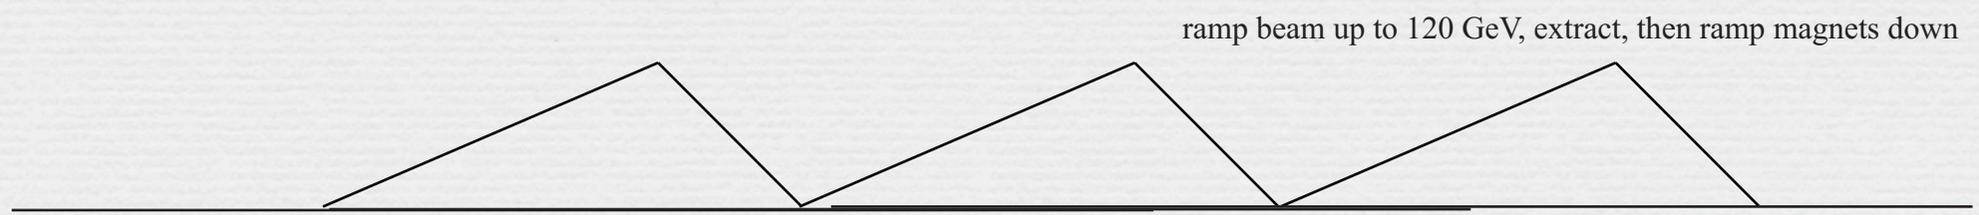

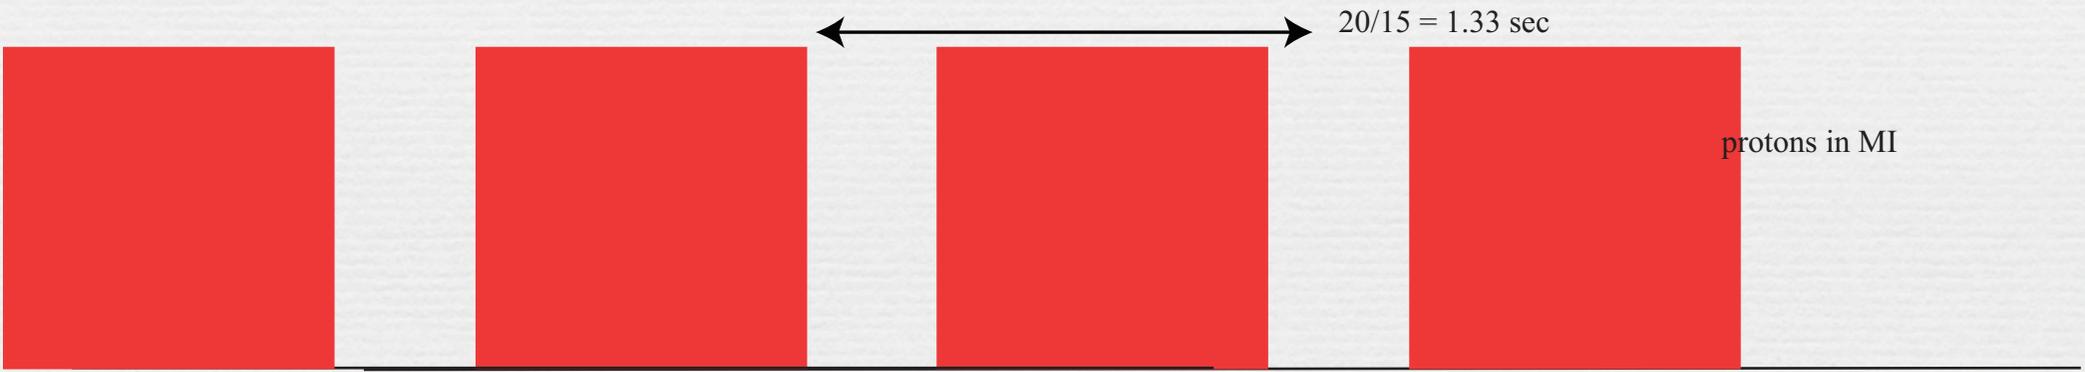

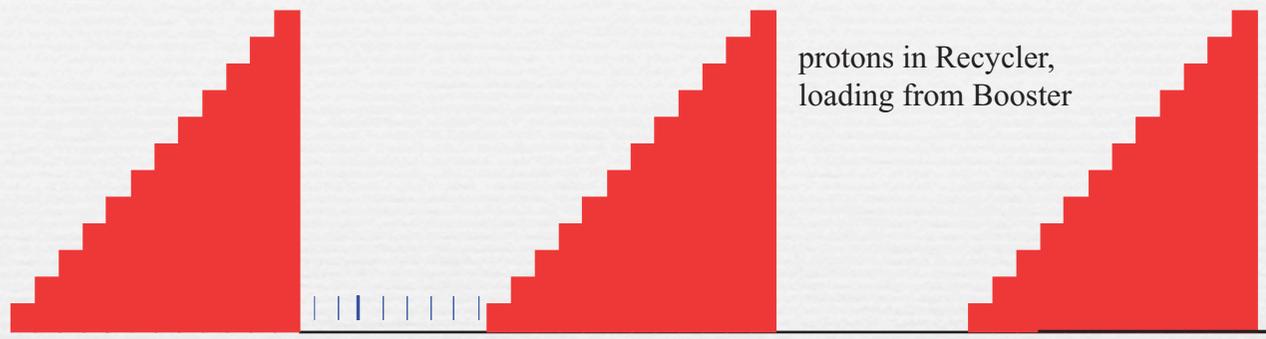

All Together...

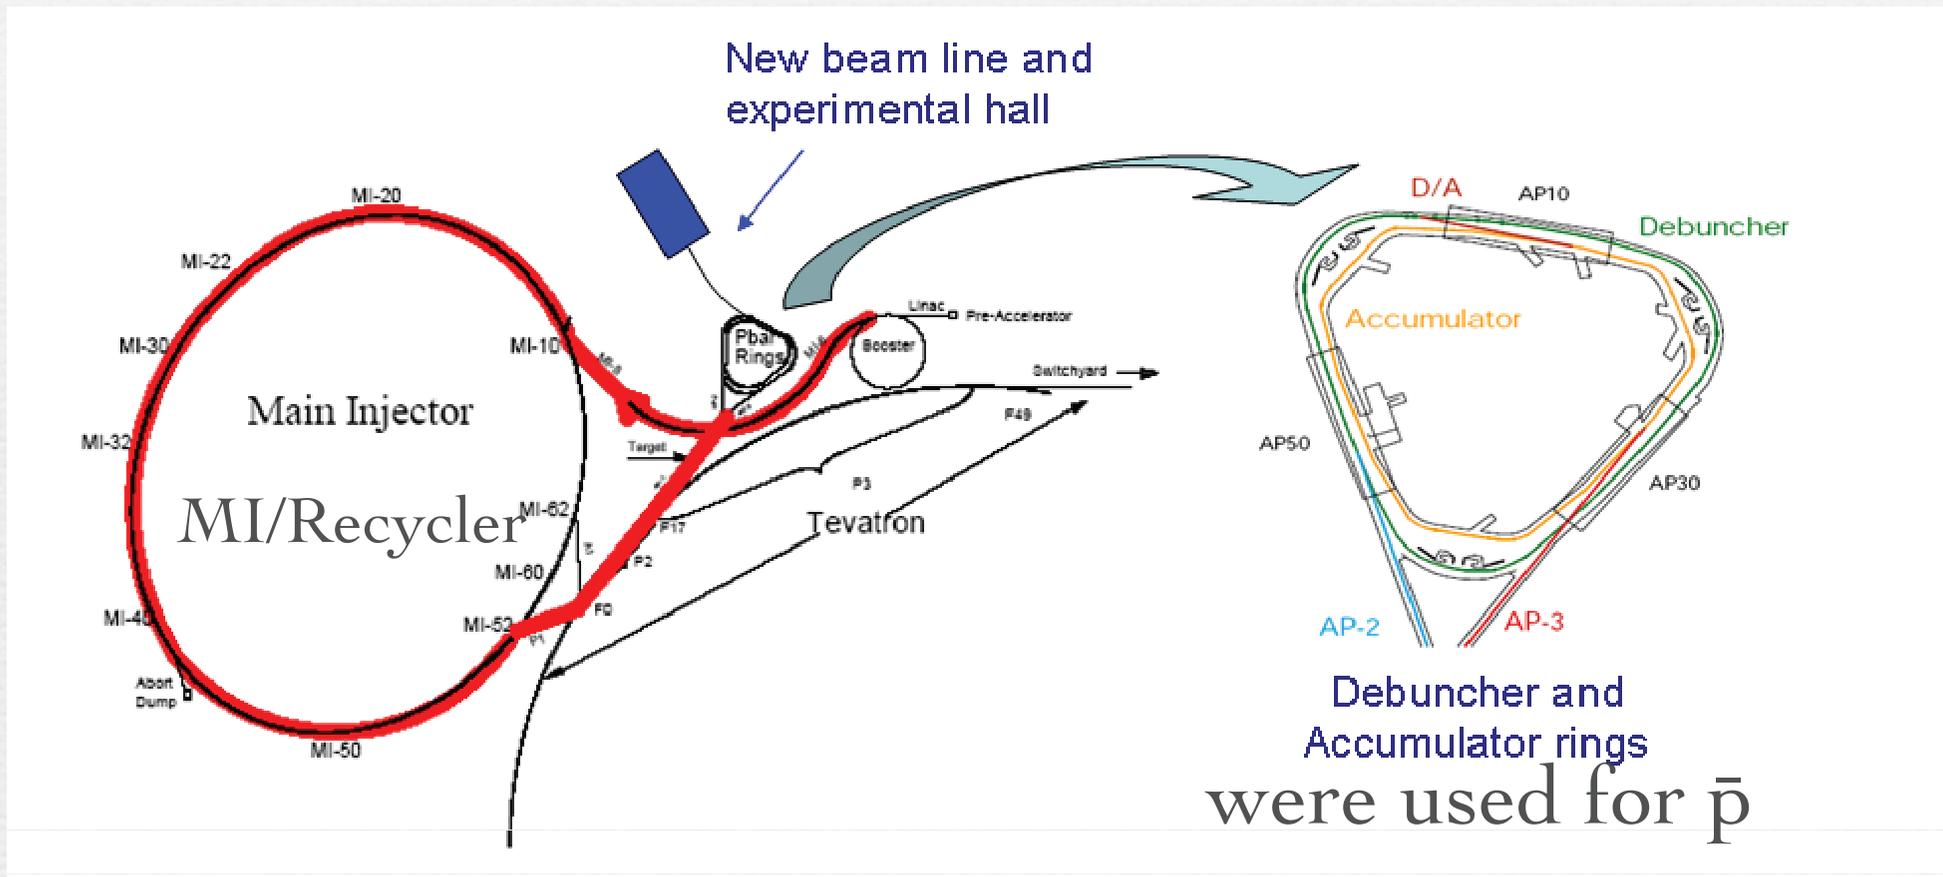

can fit eight
extra Booster
batches for us!
(can use 6)

Booster-Era (before Project X)

- After Tevatron shut-down, Accumulator, Debuncher, and Recycler “freed” from antiprotons

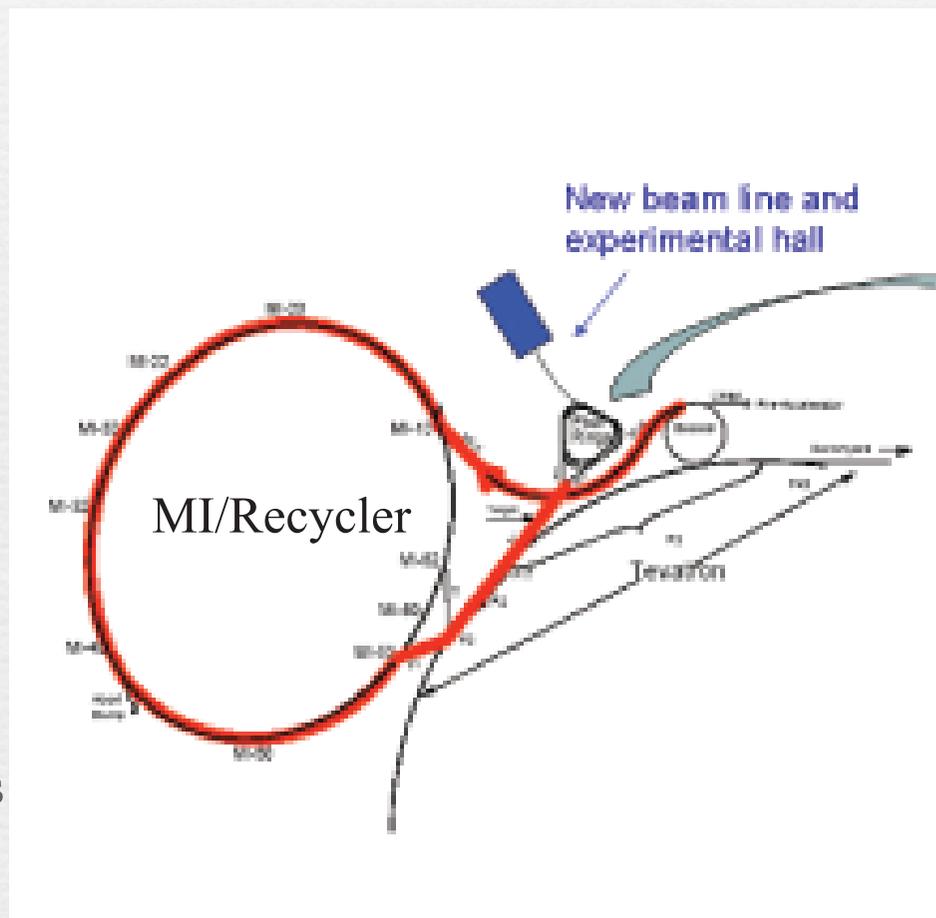

“Boomerang Scheme”

- ☛ Booster Batches transported partway through Recycler and injected directly into Accumulator
- ☛ “Momentum-Stack” batches in Accumulator
- ☛ Transfer to Debuncher
- ☛ Rebunch into Single Bunch:
 - ☛ 38 nsec RMS, ± 200 MeV
- ☛ Slow Extraction: transverse, yields bunch “train”

one scheme—there are others

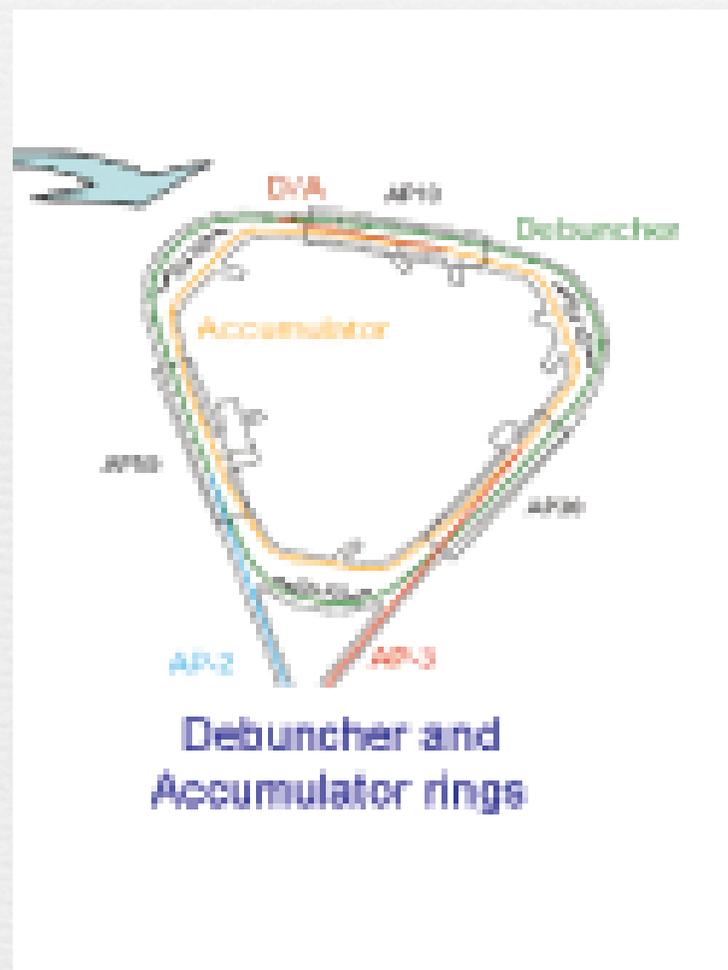

“Boomerang Scheme”

- Booster Batches transported partway through Recycler and injected directly into Accumulator
- “Momentum-Stack” batches in Accumulator
- Transfer to Debuncher
- Rebunch into Single Bunch:
 - 38 nsec RMS, ± 200 MeV
- Slow Extraction: transverse, yields bunch “train”

one scheme—there are others

- “Momentum-Stack” batches in Accumulator
- Transfer to Debuncher
- Rebunch into Single Bunch:
 - 38 nsec RMS, ± 200 MeV
- Slow Extraction: transverse, yields bunch “train”

one scheme—there are others

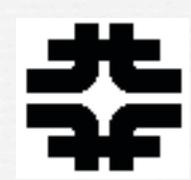

Numerically,

- can get 8 Booster Batches every 1.33 sec MI cycle, or $4.8E20/\text{yr}$ ($4E12/\text{Booster Batch}$) from Booster
 - currently 10.5 Hz in Booster, need 15 Hz
 - limits of Booster RF and radiation can be overcome with some work
 - # of batches limited by longitudinal emittance in A/D to 6 of 8 ($84 \times .038 \text{ ev-sec}$)
 - Assume $3.6E20 = (6/8 \times 4.8)$ in planning
- This manipulation can produce out-of-bucket beam
- ∴ extinction is important: must be controlled and measured

Project X Upgrades

- Ultimate sensitivity would be provided by Project X linac as proton source
 - Deliver up to 200 kW average beam current:
 - $\sim 3 \times 10^{14}$ protons/sec at 8 GeV (x10 previous slide)
 - 9mA, 1 msec, 5 Hz
- Three Upgrades for x10 from 200 kW to 2000 kW at 8 GeV:
 - Increase Pulse Length
 - Increase Repetition Rate
 - Increase Number of Klystrons

Project X Upgrades

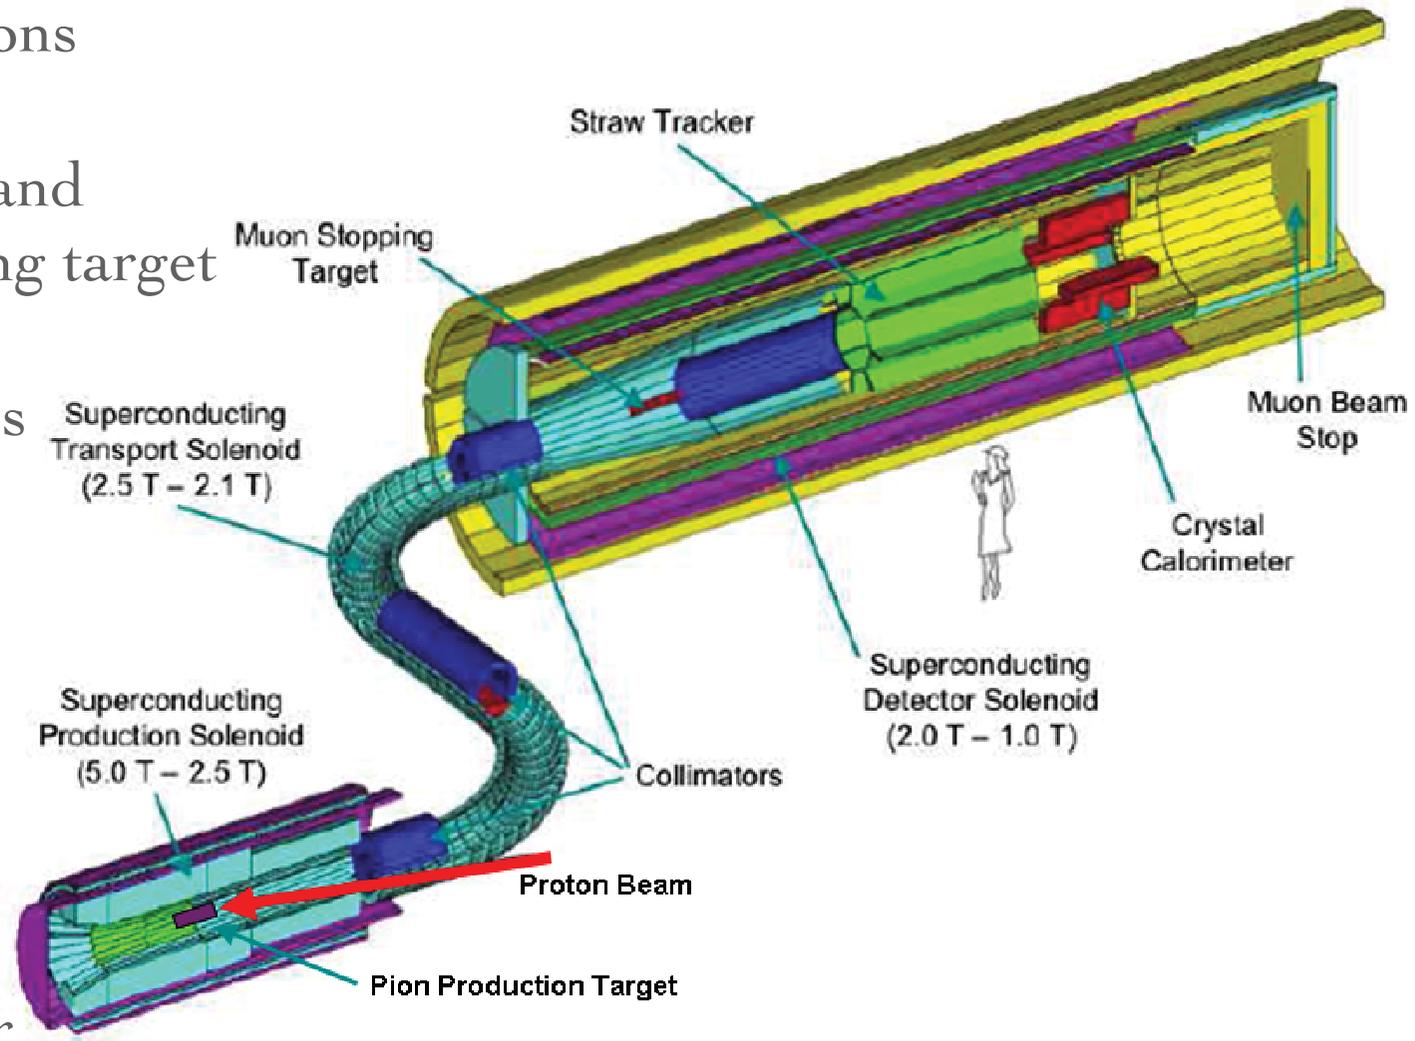

- Ultimate sensitivity would be provided by Project X linac as proton source
 - Deliver up to 200 kW average beam current:
 - $\sim 3 \times 10^{14}$ protons/sec at 8 GeV (x10 previous slide)
 - 9mA, 1 msec, 5 Hz
- Three Upgrades for x10 from 200 kW to 2000 kW at 8 GeV:
 - Increase Pulse Length
 - Increase Repetition Rate
 - Increase Number of Klystrons

**need to understand how
to push single-event
sensitivity to use
additional capability**

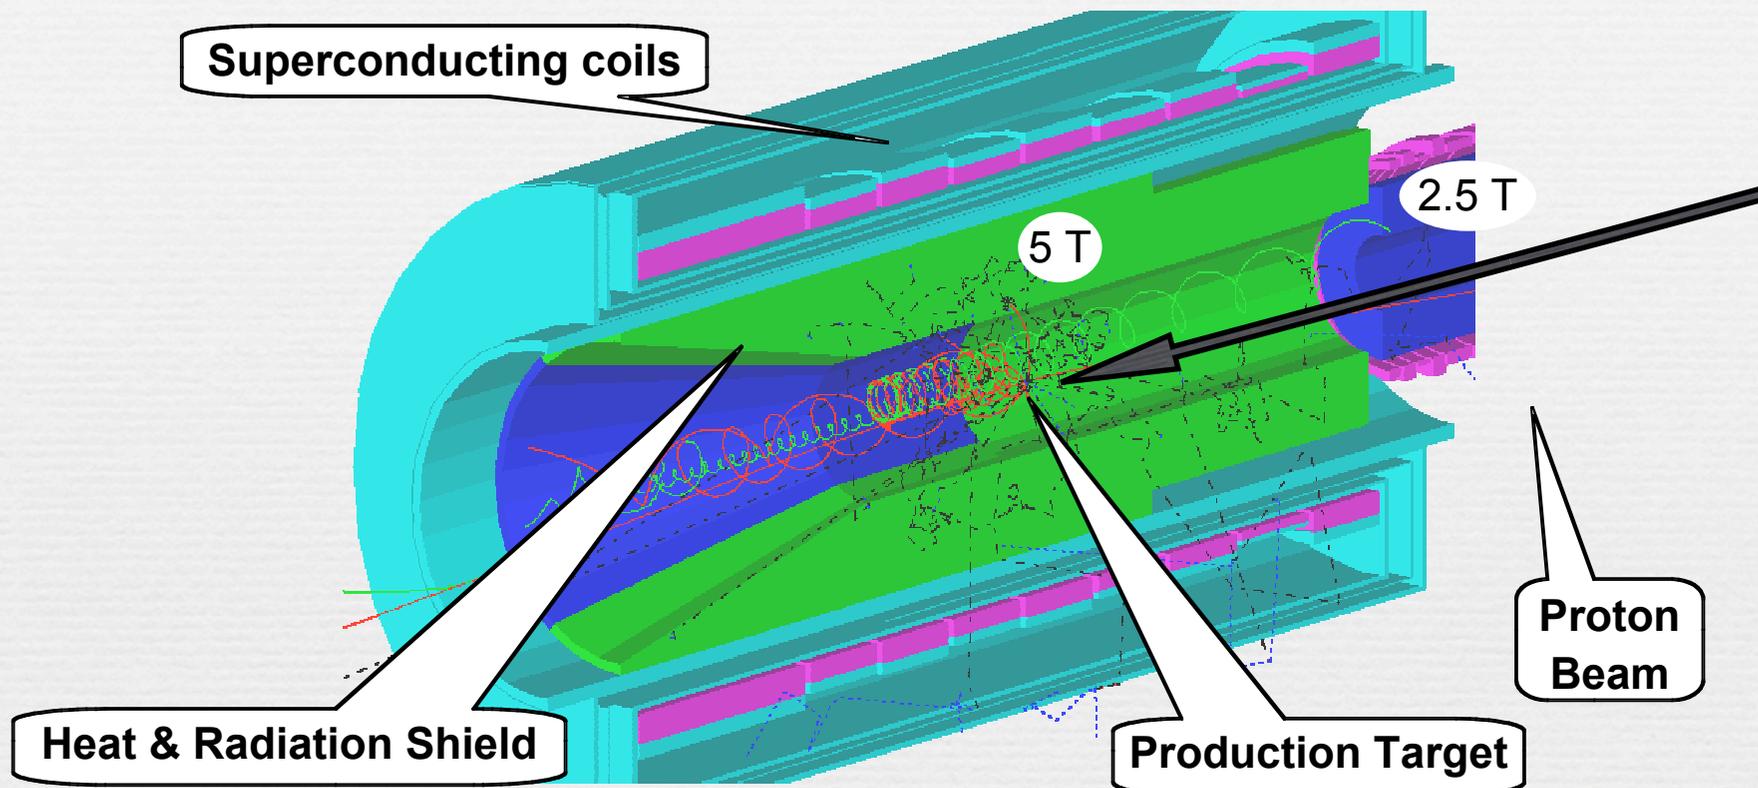

Overview of Experiment

- Magnetic bottle trapping backward-going pions
- Decay into muons and transport to stopping target
- “S”-curve eliminates backgrounds
- Thin windows for antiprotons
- Tracking
- Crystal Calorimeter

Production Region

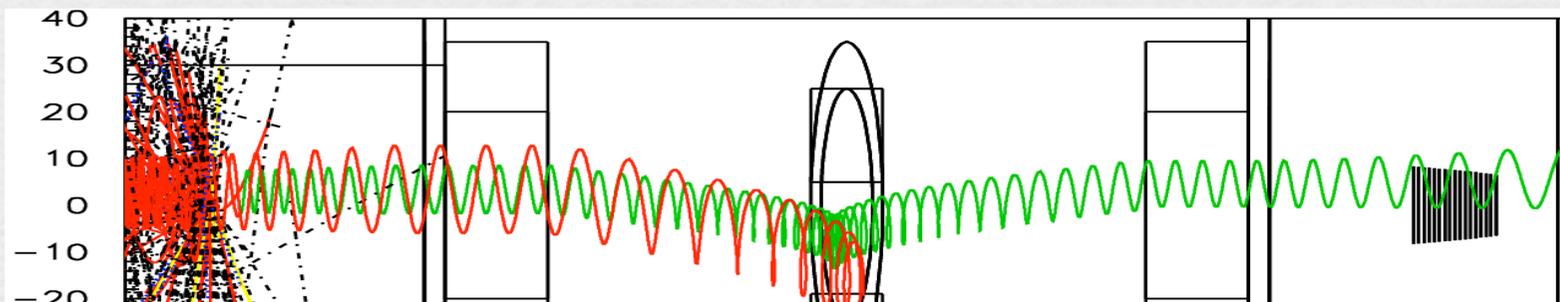

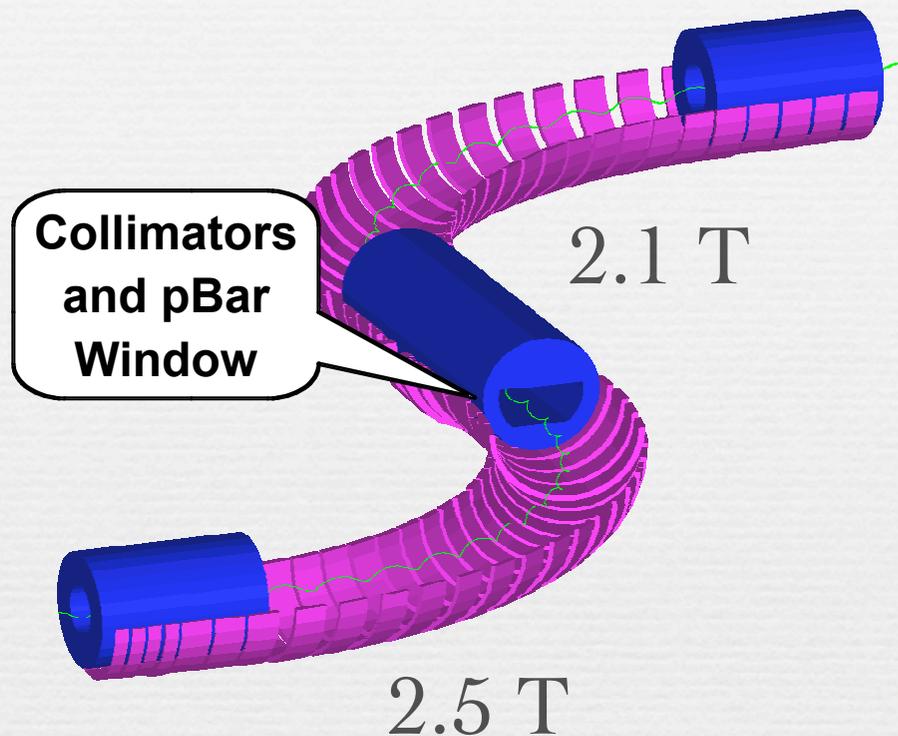

- Axially graded 5 T solenoid captures low energy backward and reflected pions and muons, transporting them toward the stopping target
- Cu and W heat and radiation shield protects superconducting coils from effects of 50kW primary proton beam: need upgrade from MECO design for > 50 kW

Transport Solenoid

- Curved solenoid eliminates line-of-sight transport of photons and neutrons
- Curvature drift and collimators sign and momentum select beam
- $dB/ds < 0$ in the straight sections to avoid trapping which would result in long transit time

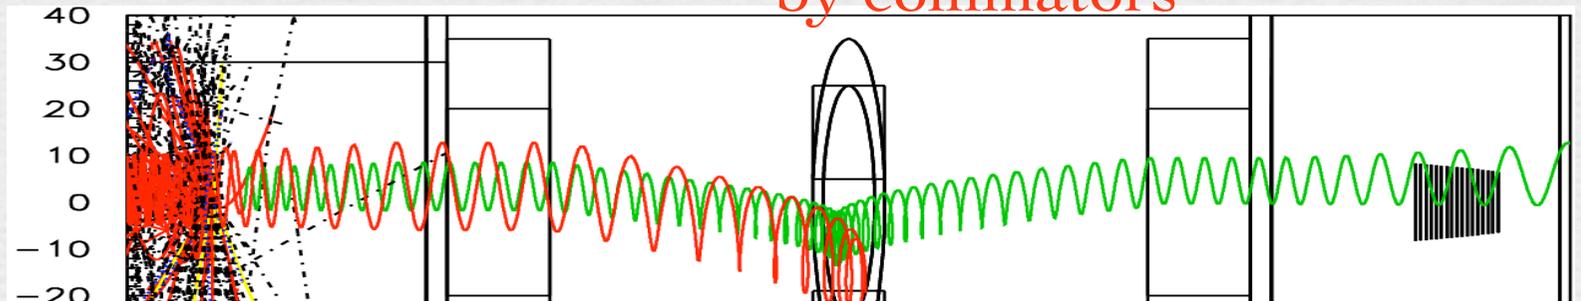

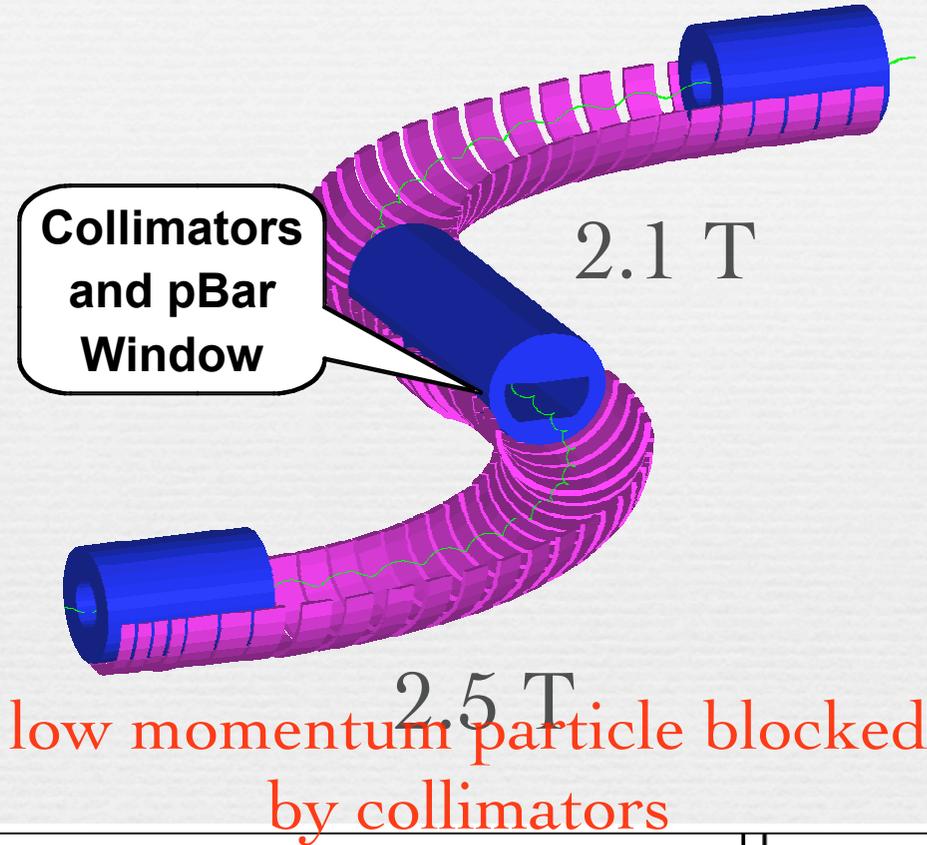

Transport Solenoid

- Curved solenoid eliminates line-of-sight transport of photons and neutrons
- Curvature drift and collimators sign and momentum select beam
- $dB/ds < 0$ in the straight sections to avoid trapping which would result in long transit time

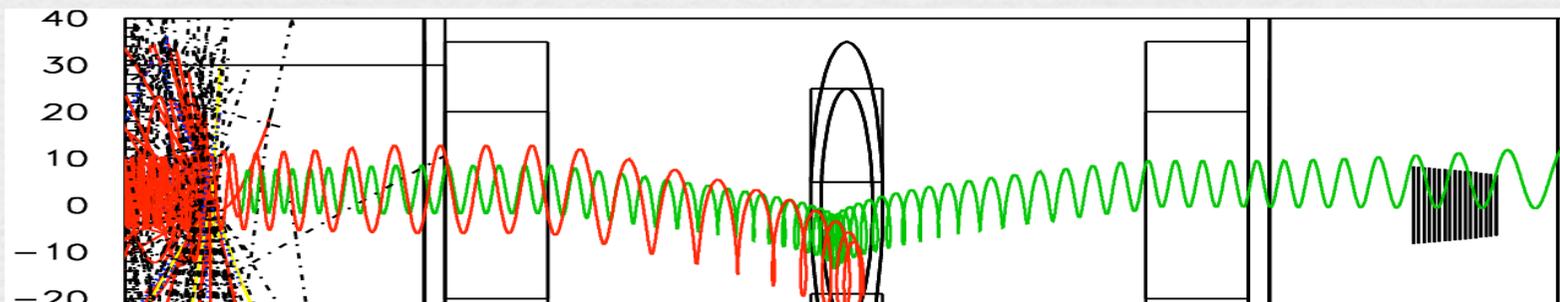

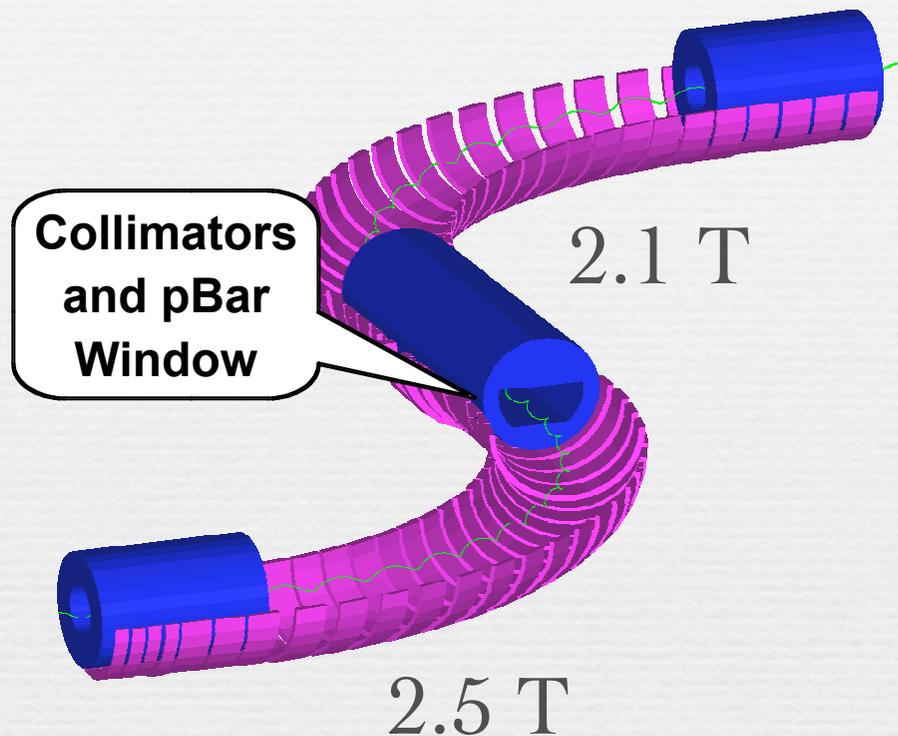

Transport Solenoid

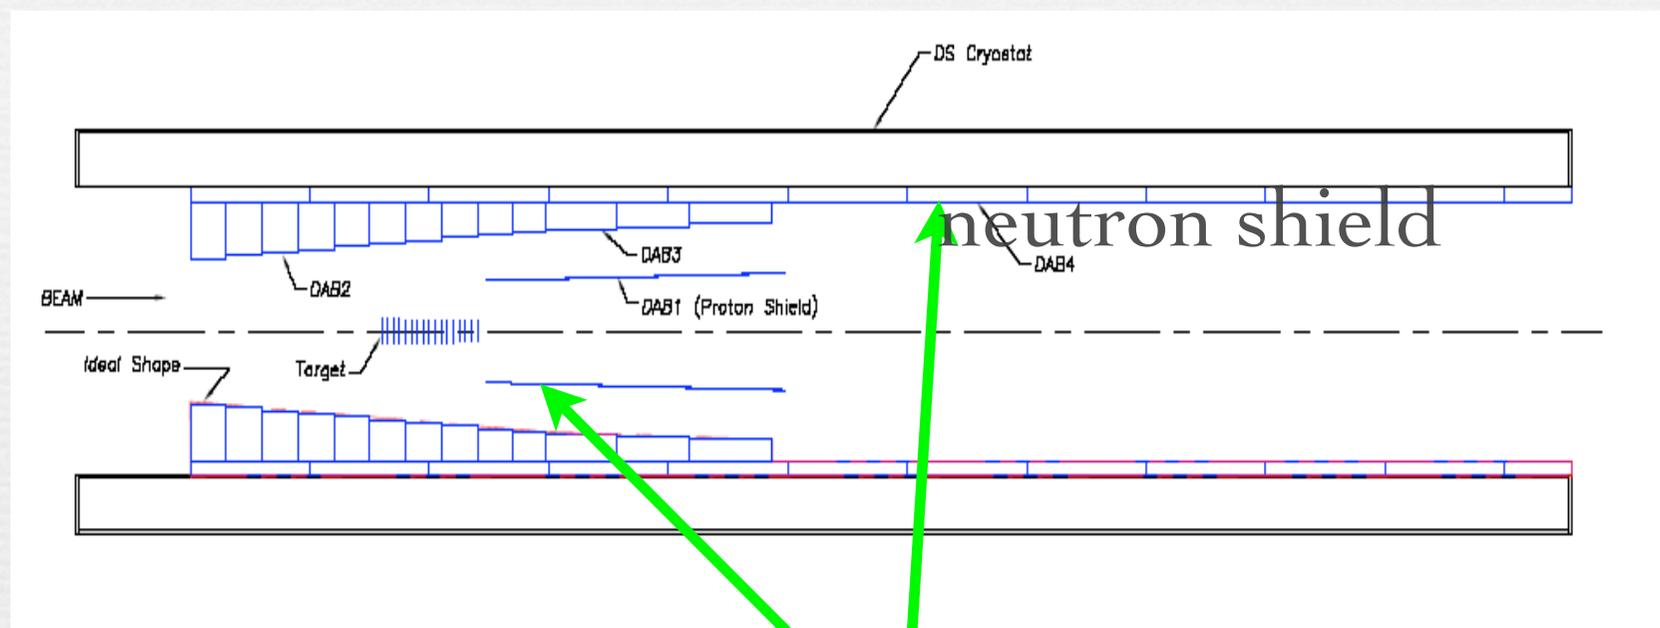

- Curved solenoid eliminates line-of-sight transport of photons and neutrons
- Curvature drift and collimators sign and momentum select beam
- $dB/ds < 0$ in the straight sections to avoid trapping which would result in long transit time

Stopping Target Region

CH2 shields

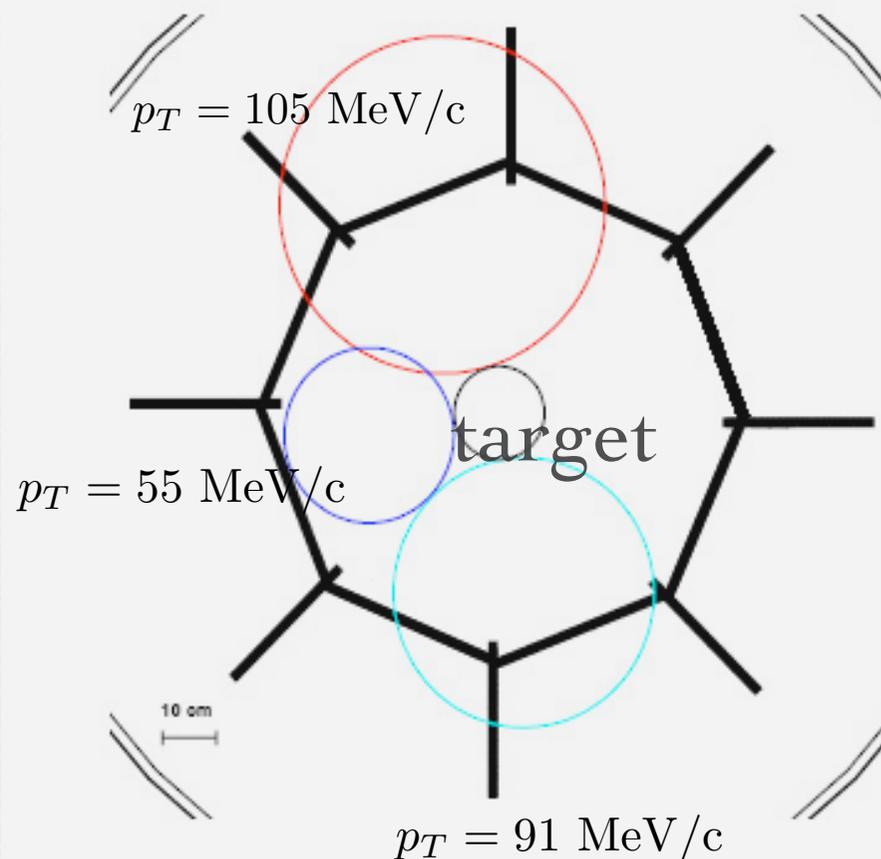

- ❧ Conical Shield Reduces background and high rate from protons produced in stopping target
- ❧ Outer shield absorbs neutron cloud

Beam's Eye View of Tracker

- Octagon and Vanes of Straw Tubes
- Immersed in solenoidal field
- Below $p_T = 55 \text{ MeV}$, electron stays inside tracker and is not seen
- Looking for helix as particle propagates downstream

Note: $<0.3\%$ of e^- from DIO have $p_T > 55 \text{ MeV}/c$

Detector

- Octagon and Vanes of Straw Tubes

$\sigma = 200 \mu$ transverse, 1.5 mm axially

2800 axial straw tubes, 2.6 m by 5 mm, 25 μ thick

- Immersed in solenoidal field, so particle follows near-helical path

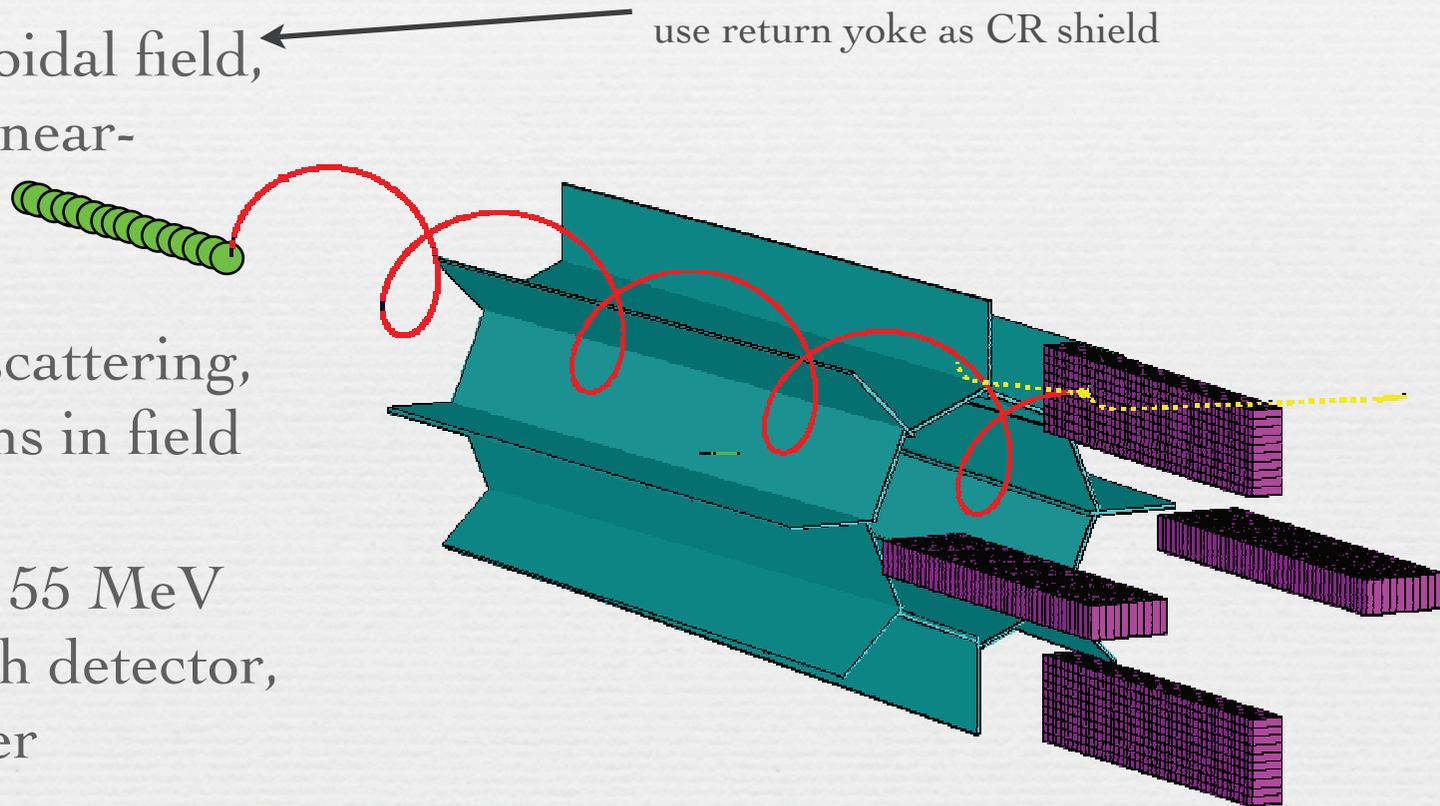

use return yoke as CR shield

- up to dE/dx , scattering, small variations in field

- Particles with $p_T < 55 \text{ MeV}$ do not pass through detector, but down the center

- Followed by Calorimeter

$\sigma/E = 5\%$, 1200 3.5 X 3.5 X 12 cm PbWO_4

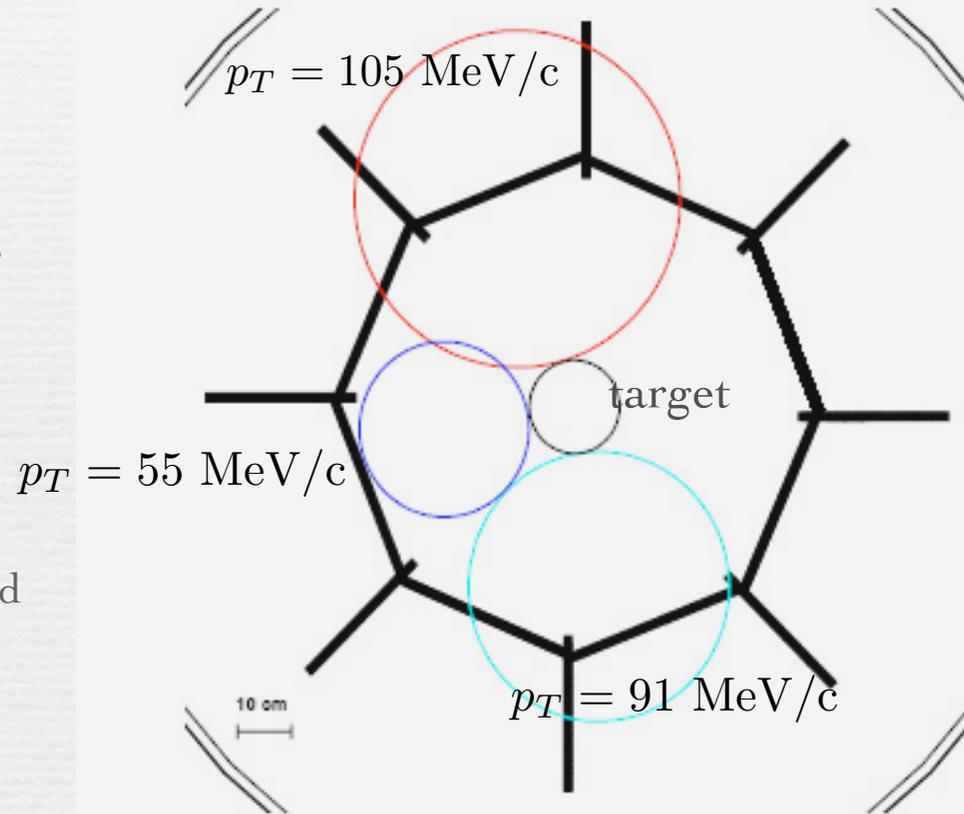

Details

- 38 -70 cm active radius
- Geometry: Octagon with eight vanes, each ~30 cm wide x 2.6 m long
- Straws: 2.9 m length 5mm dia., 25 mm wall thickness to minimize multiple scattering – 2800 total
- Three layers per plane, outer two resistive, inner conducting
- Pads: 30 cm 5mm wide cathode strips affixed to outer straws - 16640 total pads
- Position Resolution: 0.2 mm (r,φ) X 1.5 mm (z) per hit is goal
- Energy loss and straggling in the target and multiple scattering in the chambers dominate energy resolution of 1 MeV FWHM

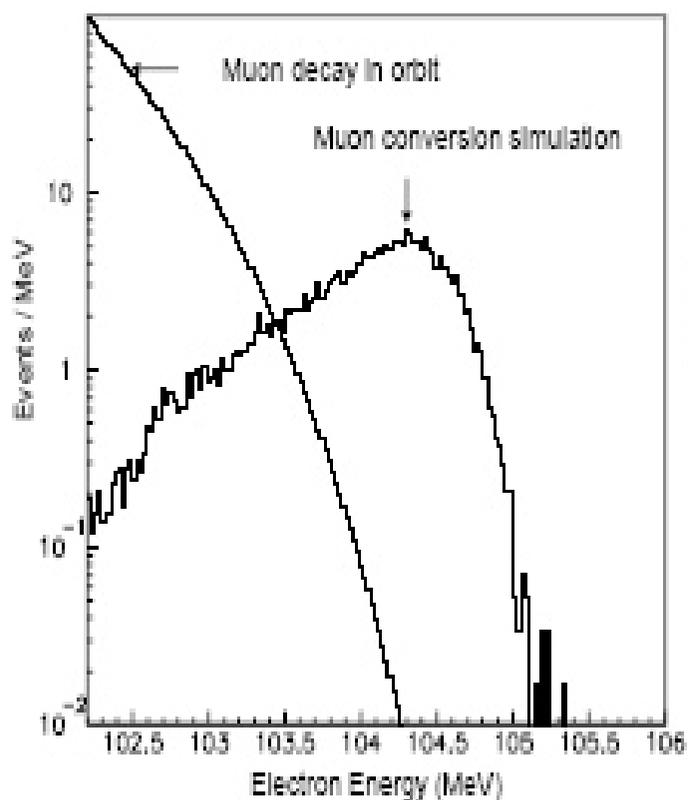

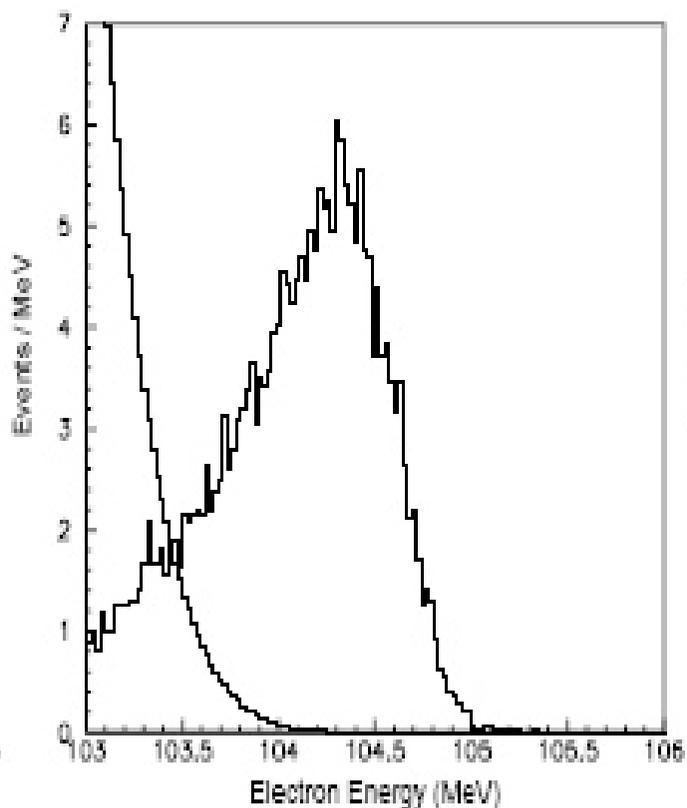

Decay-In-Orbit

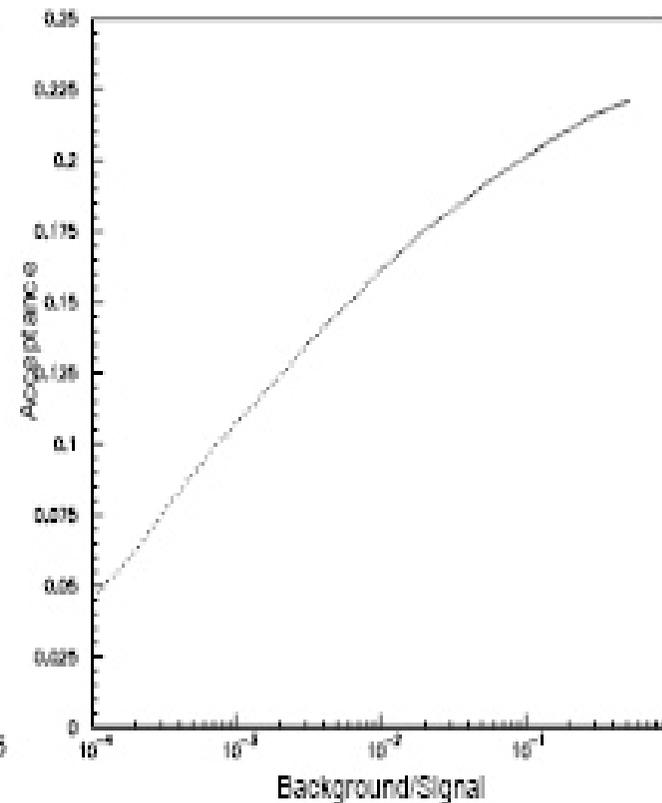

- $R_{e\mu} = 1 \times 10^{-16}$, Momentum resolution 1 MeV (FWHM)

Log scale

Linear scale

Acceptance and S/B as E_{thresh} varied

π DIF	<0.004

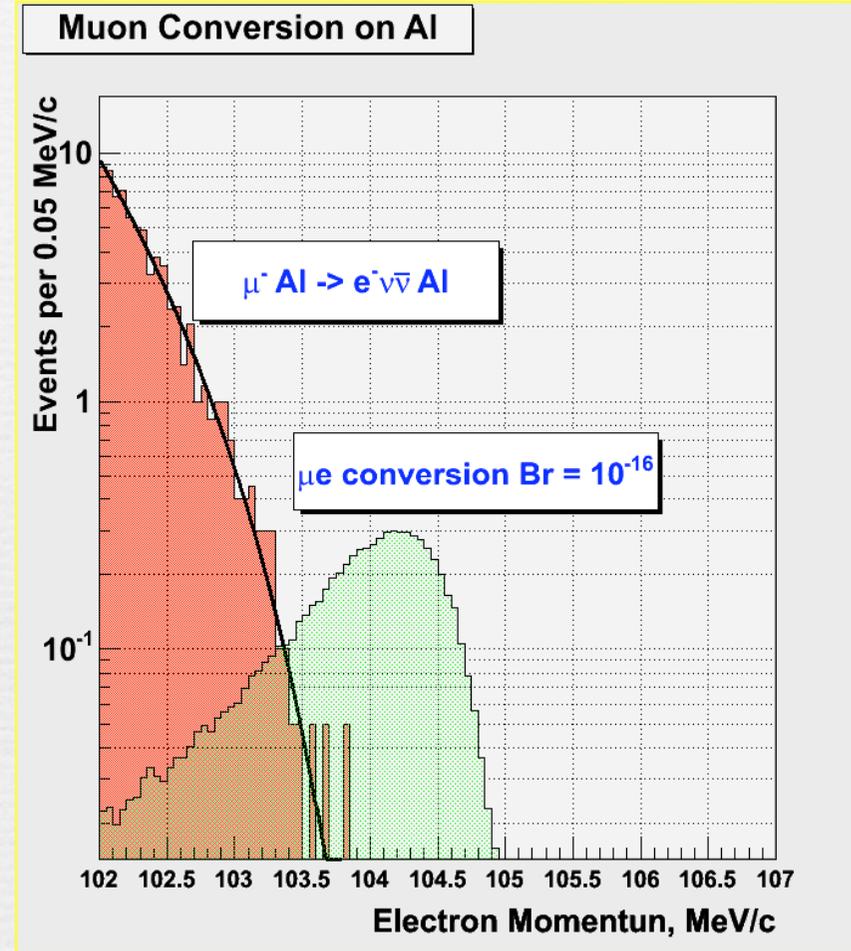

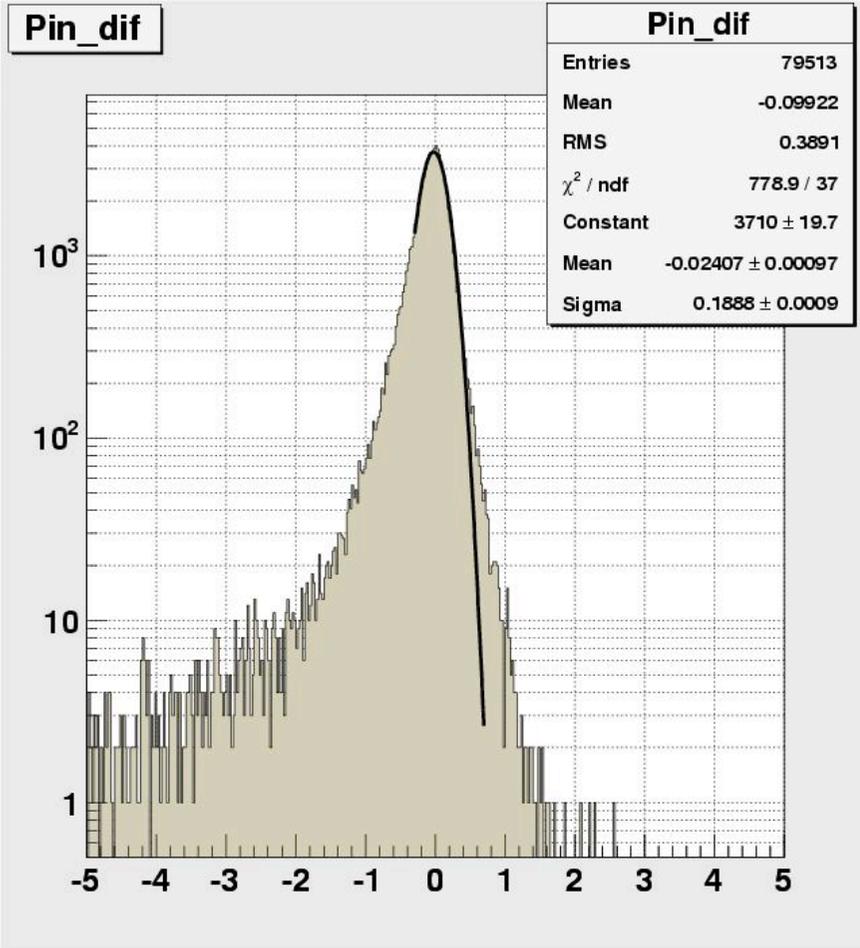

Summary of Capabilities

Resolution

Sensitivity

Cost and Schedule

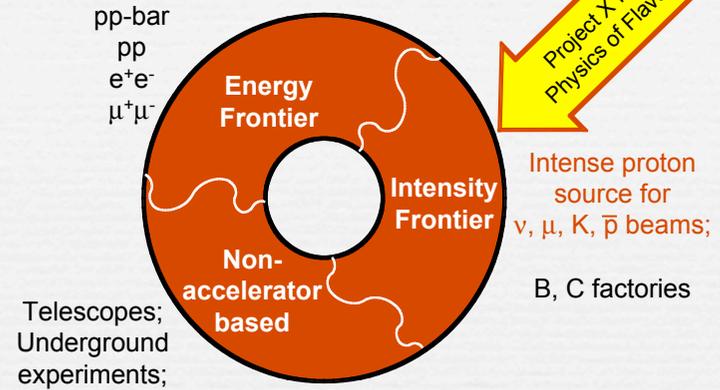

~\$100M

~2014

- ❧ A detailed cost estimate of the MECO experiment had been done just before it was cancelled:
 - ❧ Solenoids and cryogenics: \$58M
 - ❧ Remainder of experimental apparatus: \$27M
 - ❧ Additional Fermilab costs have not been worked out in detail. Recent Project X era planning exercise gives ~ \$130M total cost.
- ❧ Hope to begin Accelerator work along with NOvA: upgrade ~2010 (or 2011 if Run II extended)
 - ❧ Based on the original MECO proposal, we believe the experiment could be operational within five years from the start of significant funding
 - ❧ Driven by magnet construction.
- ❧ With the proposed beam delivery system, the experiment could collect the nominal 3.6×10^{20} protons on target in one to two years, with no impact on NOvA

Conclusions

- The $\mu 2e$ experiment is an important measurement!
- In the initial phase (without Project X) we would either:
 - Reduce the limit for $R_{\mu e}$ by more than four orders of magnitude ($R_{\mu e} < 6 \times 10^{-17}$ @ 90% C.L.)
 - Discover unambiguous proof of Beyond Standard Model physics
- With a combination of Project X and/or improved muon transport, we could either
 - Extend the limit by up to two orders of magnitude
 - Study the details of new physics

Backup Slides

- Synergies with Neutrino Factory
- Cosmic-Ray Shield
- Acceptance of Calorimeter

Synergies with Neutrino Factory?

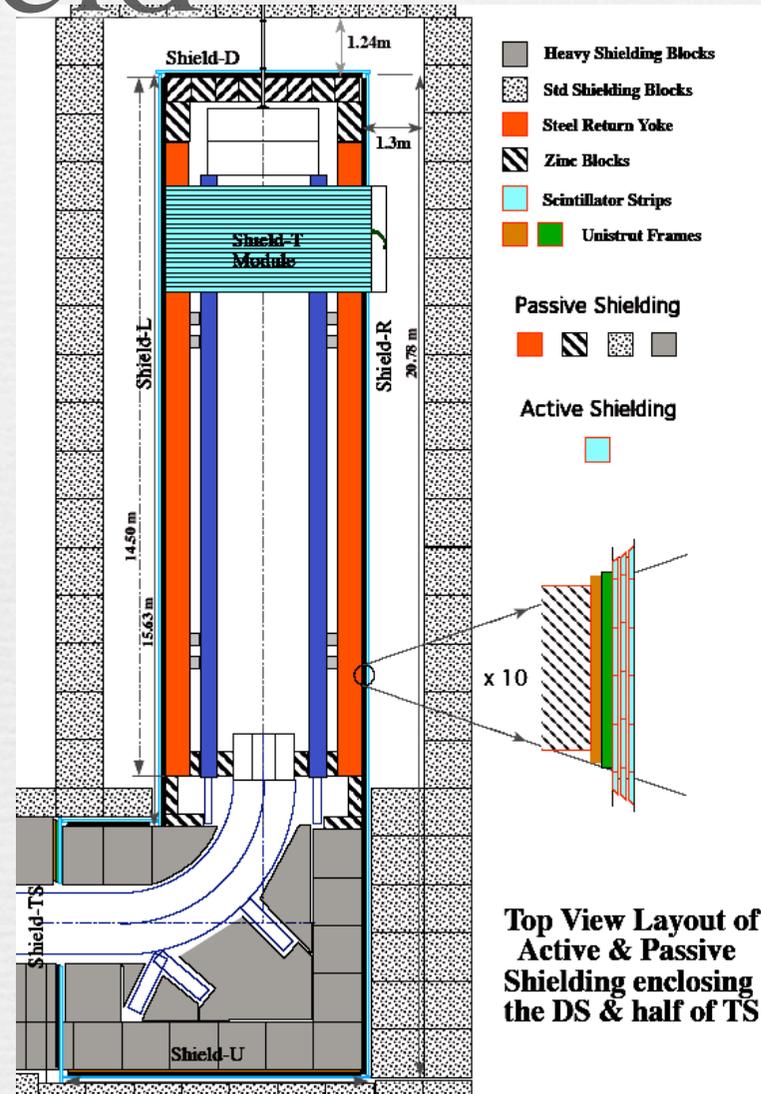

- There are a number of synergies between this project and muon cooling efforts
- The Debuncher beam could be extracted in a single turn to produce the short, intense bunch needed by muon production experiments
- Muon cooling studies have increased the understanding of solenoidal transport.
- It is possible that a “helical cooling channel”, of the sort envisioned for muon cooling, could generate a significantly higher muon yield for this experiment.
- We will investigate these in more detail for the proposal.
- **A combination of increased flux from Project X and a more efficient muon transport line could potentially result in a sensitivity as low as 10^{-18}**

Cosmic Ray/Neutron Shield

- Three Layers of Scint
 - 2/3 coincidence
 - Inefficiency $\leq 10^{-4}$

Acceptance of Calorimeter

- Note Log Scale
- High-Energy Tails of DIO do not swamp trigger
